TITLE

A HIGH SULFUR SEED PROTEIN GENE AND METHOD FOR  
INCREASING THE SULFUR AMINO ACID CONTENT OF PLANTS

5

BACKGROUND OF THE INVENTION

The worldwide animal feed market, which includes livestock, poultry, aquaculture and pets is 475 million metric tons. In the United States 180 million metric tons are consumed with corn (Zea mays L.) accounting for about 67% and soybean (Glycine max L.) meal for about 10% of the total. Corn and soybean products are also a major element of foreign trade. These two crops are agronomically well-adapted to many parts of the U.S., and machinery and facilities for harvesting, storing and processing are widely available across the U.S. Because corn, soybean and other crops used for feed are currently sold as commodities, an excellent opportunity exists to upgrade the nutritional quality of the protein and thus add value for the U.S. farmer and enhance foreign trade.

Human food and animal feed derived from many grains are deficient in the sulfur amino acids, methionine and cysteine, which are required in the animal diet. In corn, the sulfur amino acids are the third most limiting amino acids, after lysine and tryptophan, for the dietary requirements of many animals. The use of soybean meal, which is rich in lysine and tryptophan, to supplement corn in animal feed is limited by the low sulfur amino acid content of the legume. Thus, an increase in the sulfur amino acid content of either corn or soybean would improve the nutritional quality of the mixtures and reduce the need for further supplementation through addition of more expensive methionine.

Efforts to improve the sulfur amino acid content of crops through plant breeding have met with limited

success on the laboratory scale and no success on the commercial scale. A mutant corn line which had an elevated whole-kernel methionine concentration was isolated from corn cells grown in culture by selecting  
5 for growth in the presence of inhibitory concentrations of lysine plus threonine [Phillips et al. (1985) Cereal Chem. 62:213-218]. However, agronomically-acceptable cultivars have not yet been derived from this line and commercialized. Soybean cell lines with increased  
10 intracellular concentrations of methionine were isolated by selection for growth in the presence of ethionine [Madison and Thompson (1988) Plant Cell Reports 7:472-476], but plants were not regenerated from these lines.

The amino acid content of seeds is determined  
15 primarily by the storage proteins which are synthesized during seed development and which serve as a major nutrient reserve following germination. The quantity of protein in seeds varies from about 10% of the dry weight in cereals to 20-40% of the dry weight of legumes. In  
20 many seeds the storage proteins account for 50% or more of the total protein. Because of their abundance plant seed storage proteins were among the first proteins to be isolated. Only recently, however, have the amino acid sequences of some of these proteins been determined  
25 with the use of molecular genetic techniques. These techniques have also provided information about the genetic signals that control the seed-specific expression and the intracellular targeting of these proteins.

30 A number of sulfur-rich plant seed storage proteins have been identified and their corresponding genes have been isolated. A gene in corn for a 15 kD zein protein containing 11% methionine and 5% cysteine [Pedersen et al. (1986) J. Biol. Chem. 261:6279-6284] and a gene for  
35 a 10 kD zein protein containing 23% methionine and 3%

cysteine have been isolated [Kirihara et al. (1988) Mol. Gen. Genet. 21:477-484; Kirihara et al. (1988) Gene 71:359-370]. Two genes from pea for seed albumins containing 8% and 16% cysteine have been isolated  
5 [Higgins et al. (1986) J. Biol. Chem. 261:11124-11130]. A gene from Brazil nut for a seed 2S albumin containing 18% methionine and 8% cysteine has been isolated [Altenbach et al. (1987) Plant Mol. Biol. 8:239-250]. Finally, from rice a gene coding for a 10 kD seed  
10 prolamin containing 19% methionine and 10% cysteine has been isolated [Masumura et al. (1989) Plant Mol. Biol. 12:123-130].

There have been many reports on the expression of seed storage protein genes in transgenic plants. The  
15 high-sulfur 2S albumin from Brazil nut has been expressed in the seeds of transformed tobacco under the control of the regulatory sequences from a bean phaseolin storage protein gene. The protein was efficiently processed from a 17 kD precursor to the 9 kD  
20 and 3 kD subunits of the mature native protein. The accumulation of the methionine-rich protein in the tobacco seeds resulted in an up to 30% increase in the level of methionine in the seeds [Altenbach et al. (1989) Plant Mol. Biol. 13:513-522]. Chimeric genes  
25 linking the coding regions of corn seed storage protein genes for 19 and 23 kD zeins to the Cauliflower Mosaic virus 35S promoter were expressed at very low levels in seeds, as well as roots and leaves, of transformed tobacco [Scherthaner et al. (1988) EMBO J. 7:1249-  
30 1255]. Replacement of the monocot regulatory regions (promoter and transcription terminator) with dicot seed-specific regulatory regions resulted in low level seed-specific expression of a 19 kD zein in transformed  
petunia [Williamson et al. (1988) Plant Physiol. 88:1002-1007] and tobacco [Ohtani et al. (1991) Plant  
35

Mol. Biol. 16:117-128]. In another case, high-level seed-specific expression of the 15 kD sulfur-rich zein was found in transformed tobacco, and the signal sequence of the monocot precursor was also correctly  
5 processed [Hoffman et al. (1987) EMBO J. 6:3213-3221].

In order to increase the sulfur amino acid content of seeds it is essential to isolate a gene(s) coding for seed storage proteins that are rich in the sulfur-containing amino acids methionine and cysteine.  
10 Methionine is preferable to cysteine because methionine can be converted to cysteine, but cysteine cannot be converted to methionine by most animals. It is desirable that the storage protein be compatible with those of the target crop plant. Furthermore, it is  
15 desirable that the protein come from a source that is generally regarded as safe for animal feed.

#### SUMMARY OF THE INVENTION

A means to increase the sulfur amino acid content of seeds has been discovered. Using the High Sulfur  
20 Zein (HSZ) gene chimeric genes may be created and used to transform various crop plants to increase the sulfur amino acid content of the seeds or leaves.

Specifically, one aspect of the present invention is a nucleic acid fragment comprising a nucleotide sequence  
25 encoding the HSZ corn storage protein precursor corresponding to the sequence shown in SEQ ID NO:2:, or any nucleotide sequence substantially homologous therewith. Other aspects of the invention are those nucleic acid fragments encoding the mature HSZ protein  
30 (SEQ ID NO:3:) and encoding the High Methionine Domain (HMD) of the HSZ corn storage protein (SEQ ID NO:4:).

Other embodiments of this invention are chimeric genes capable of being expressed in transformed plants comprising any of the preceding nucleic acid fragments  
35 operably linked to regulatory sequences. Preferred are

those chimeric genes which operably link the nucleic acid fragments to seed-specific promoters or promoters active in leaves of corn or soybean.

Another aspect of this invention is chimeric genes  
5 capable of being expressed in transformed  
microorganisms, preferably *E. coli*, to produce high  
sulfur proteins.

Yet another aspect of this invention are host cells  
transformed by chimeric genes to produce high sulfur  
10 proteins.

Yet other embodiments of the invention are  
transformed plants and the seeds derived from them  
containing any of the preceding nucleic acid fragments.  
Preferred are plants and the seeds derived from them  
15 selected from the group consisting of corn, soybeans,  
rapeseed, tobacco and rice.

Additional aspects of the invention are  
microorganisms transformed with the disclosed chimeric  
genes.

20 Further embodiments of the invention are methods  
for increasing the sulfur amino acid content of plants  
and *Agrobacterium tumefaciens* mediated methods for  
producing plants with the capacity to produce high  
sulfur proteins. Also encompassed within the invention  
25 are methods for producing protein rich in sulfur  
containing amino acids in a microorganism.

#### BRIEF DESCRIPTION OF THE DRAWINGS AND SEQUENCE DESCRIPTIONS

The invention can be more fully understood from the  
30 following detailed description, the accompanying  
drawings, and the Sequence Descriptions which form a  
part of this application. The Sequence Descriptions  
contain the three letter codes for amino acids as  
defined in 37 C.F.R. 1.822 which are incorporated by  
35 reference herein.

SEQ ID NO:1 shows the nucleotide sequence (2123 bp) of the corn HSZ gene and the predicted amino acid sequence of the primary translation product. Nucleotides 753-755 are the putative translation  
5 initiation codon and nucleotides 1386-1388 are the putative translation termination codon. Nucleotides 1-752 and 1389-2123 include putative 5' and 3' regulatory sequences, respectively.

SEQ ID NO:2 shows a preferred nucleotide sequence  
10 of the invention. It represents a 635 bp DNA fragment including the HSZ coding region only, which can be isolated by restriction endonuclease digestion using Nco I (5'-CCATGG) to Xba I (5'-TCTAGA). Two Nco I sites that were present in the native HSZ coding region were  
15 eliminated by site-directed mutagenesis, without changing the encoded amino acid sequence.

SEQ ID NO:3 shows a preferred nucleotide sequence of the invention. It represents a 579 bp DNA fragment including the coding region of the mature HSZ protein  
20 only, which can be isolated by restriction endonuclease digestion using BspH I (5'-TCATGA) to Xba I (5'-TCTAGA). Two Nco I sites that were present in the native HSZ coding region were eliminated by site-directed mutagenesis. This was accomplished without changing the  
25 encoded amino acid sequence.

SEQ ID NO:4 shows the nucleotide and derived amino acid sequence of the HMD gene.

SEQ ID NO:5 shows the DNA sequence of the corn  
10 kD zein gene. [Kirihara et al. (1988) Mol. Gen.  
30 Genet. 21:477-484; Kirihara et al. (1988) Gene 71:359-370].

SEQ ID NOS:6 and 7 were used in Example 1 to screen a corn library for a high methionine 10 kD zein gene.

SEQ ID NOS:8 and 9 were used in Example 2 to carry  
35 out the mutagenesis of the HSZ gene.

SEQ ID NOS:10 and 11 were used in Example 2 to create a form of the HSZ gene with alternative unique endonuclease sites.

5 SEQ ID NOS:12 and 13 were used in Example 2 to create a gene to code for the mature form of HSZ.

SEQ ID NOS:14 and 15 were used in Example 5 to construct a gene to encode the HMD of HSZ.

10 SEQ ID NOS:16-21 were used in Example 6 the construction of chimeric genes for expression of HSZ in plants.

SEQ ID NO:22 was used in Example 7 for the analysis of transformants of tobacco with the Phaseolin-HSZ chimeric genes..

15 SEQ ID NOS:23, 24 and 25 were used in Example 10 for the construction of chimeric genes for expression of HMD in plants.

20 SEQ ID NO:26 is a chimeric gene composed of the 35S promoter from Cauliflower Mosaic Virus [Odell et al.(1985) Nature 313:810-812], the hygromycin phosphotransferase gene from plasmid pJR225 (from *E. coli*) [Gritz et al.(1983) Gene 25:179-188] and the 3' region of the nopaline synthase gene from the T-DNA of the Ti plasmid of *Agrobacterium tumefaciens* used as a selectable genetic marker for transformation of soybean  
25 in Example 11.

SEQ ID NO:27 is the central region of the HSZ protein.

30 SEQ ID NO:28 is an amino acid sequence for the retention of proteins in the lumen of the endoplasmic reticulum.

Figure 1 shows a comparison of the amino acid sequences of the 10 kD zein (SEQ ID NO:5) and HSZ (SEQ ID NO:2). Single letter codes for amino acids are used. High methionine domains of the two proteins are

underlined. The vertical lines in Figure 1 indicate identical amino acid residues in the two proteins.

Figure 2 shows a schematic representation of seed-specific gene expression cassettes useful for  
5 constructing chimeric genes for expression of HSZ in transgenic plants.

Figure 3 shows a map of the binary plasmid vector pZS97K.

Figure 4 shows a map of the binary plasmid vector  
10 pZS97.

#### DETAILED DESCRIPTION OF THE INVENTION

The present invention describes nucleic acid fragments that encode a corn High Sulfur Zein (HSZ) seed storage protein or a High Methionine Domain (HMD)  
15 derived from HSZ, both of which are unusually rich in the amino acid methionine.

The HSZ protein is composed of a central very-methionine-rich region (approximately 48% methionine residues) flanked by amino terminal and carboxy terminal  
20 regions with lower methionine content (10% methionine and 7% methionine, respectively). The central region is composed of variations of the repeating motif Met-Met-Met-Pro (SEQ ID NO:27). The related 10 kD zein protein has a similar but distinct structure (see Figure 1).  
25 However the central region of the HSZ protein is about twice as large as the corresponding region in the 10 kD zein, accounting for the increased methionine content of HSZ. The apparent duplication of the central high methionine domain (HMD) in HSZ compared to 10 kD zein  
30 suggested that the central high methionine domain might have a stable structure and could be expressed by itself, yielding a very high methionine storage protein.

The introduction of a chimeric gene comprising seed storage protein regulatory sequences and methionine-rich  
35 seed storage protein coding sequence represents an

approach to improve the nutritional quality of seeds from crop plants. The increase in methionine content of the seed will be determined by: (a) the level of expression of the chimeric gene in the transformed crop, which depends, in part, upon the seed-specific expression signals used, (b) the percentage of methionine residues in the seed storage protein coding region, (c) the stability of the introduced protein in the seed of the transformed crop plant, which depends, in part, upon its proper processing, intracellular targeting, assembly into higher-order structures in some cases, and ability to withstand dessication, and (d) the compatibility of the introduced protein with the native seed proteins of the transformed crop.

Transfer of the nucleic acid fragments of the invention, with suitable regulatory sequences, into a living cell will result in the production or overproduction of the protein. Transfer of the nucleic acid fragments of the invention into a plant, particularly corn, soybean or oilseed rape, with suitable regulatory sequences to direct expression of the protein in the seeds may result in an increased level of sulfur-containing amino acids, particularly methionine, and thus improve the nutritional quality of the seed protein for animals.

In the context of this disclosure, a number of terms shall be utilized. As used herein, the term "nucleic acid" refers to a large molecule which can be single-stranded or double-stranded, composed of monomers (nucleotides) containing a sugar, phosphate and either a purine or pyrimidine. A "nucleic acid fragment" is a fraction of a given nucleic acid molecule. In higher plants, deoxyribonucleic acid (DNA) is the genetic material while ribonucleic acid (RNA) is involved in the transfer of the information in DNA into proteins. A

"genome" is the entire body of genetic material contained in each cell of an organism. The term "nucleotide sequence" refers to a polymer of DNA or RNA which can be single- or double-stranded, optionally  
5 containing synthetic, non-natural or altered nucleotide bases capable of incorporation into DNA or RNA polymers.

As used herein, the term "homologous to" refers to the complementarity between the nucleotide sequence of two nucleic acid molecules or between the amino acid  
10 sequences of two protein molecules. Estimates of such homology are provided by either DNA-DNA or DNA-RNA hybridization under conditions of stringency as is well understood by those skilled in the art [as described in Hames and Higgins (eds.) Nucleic Acid Hybridisation, IRL  
15 Press, Oxford, U.K.]; or by the comparison of sequence similarity between two nucleic acids or proteins.

As used herein, "substantially homologous" refers to nucleic acid molecules which require less stringent conditions of hybridization than those for homologous  
20 sequences, and also refers to coding DNA sequence which may involve base changes that do not cause a change in the encoded amino acid, or which involve base changes which may alter one or more amino acids, but not affect the functional properties of the protein encoded by the  
25 DNA sequence. Thus, the nucleic acid fragments described herein include molecules which comprise possible variations of the nucleotide bases derived from deletion, rearrangement, random or controlled mutagenesis of the nucleic acid fragment, and even  
30 occasional nucleotide sequencing errors so long as the DNA sequences are substantially homologous.

"Gene" refers to a nucleic acid fragment that expresses a specific protein, including regulatory sequences preceding (5' non-coding) and following (3'  
35 non-coding) the coding region. "Native" gene refers to

the gene as found in nature with its own regulatory sequences. "Chimeric" gene refers to a gene comprising heterogeneous regulatory and coding sequences.

"Endogenous" gene refers to the native gene normally found in its natural location in the genome. A "foreign" gene refers to a gene not normally found in the host organism but that is introduced by gene transfer.

"Coding sequence" refers to a DNA sequence that codes for a specific protein and excludes the non-coding sequences. It may constitute an "uninterrupted coding sequence", i.e., lacking an intron, such as in a cDNA or it may include one or more introns bounded by appropriate splice junctions. An "intron" is a sequence of RNA which is transcribed in the primary transcript but which is removed through cleavage and re-ligation of the RNA within the cell to create the mature mRNA that can be translated into a protein.

"Initiation codon" and "termination codon" refer to a unit of three adjacent nucleotides in a coding sequence that specifies initiation and chain termination, respectively, of protein synthesis (mRNA translation). "Open reading frame" refers to the amino acid sequence encoded between translation initiation and termination codons of a coding sequence.

"RNA transcript" refers to the product resulting from RNA polymerase-catalyzed transcription of a DNA sequence. When the RNA transcript is a perfect complementary copy of the DNA sequence, it is referred to as the primary transcript or it may be a RNA sequence derived from posttranscriptional processing of the primary transcript and is referred to as the mature RNA. "Messenger RNA" (mRNA) refers to the RNA that is without introns and that can be translated into protein by the

cell. "cDNA" refers to a double-stranded DNA that is complementary to and derived from mRNA.

As used herein, "regulatory sequences" refer to nucleotide sequences located upstream (5'), within, and/or downstream (3') to a coding sequence, which control the transcription and/or expression of the coding sequences, potentially in conjunction with the protein biosynthetic apparatus of the cell. These nucleotide sequences include a promoter sequence, a translation leader sequence, a transcription termination sequence, and a polyadenylation sequence.

"Promoter" refers to a DNA sequence in a gene, usually upstream (5') to its coding sequence, which controls the expression of the coding sequence by providing the recognition for RNA polymerase and other factors required for proper transcription. A promoter may also contain DNA sequences that are involved in the binding of protein factors which control the effectiveness of transcription initiation in response to physiological or developmental conditions. It may also contain enhancer elements.

An "enhancer" is a DNA sequence which can stimulate promoter activity. It may be an innate element of the promoter or a heterologous element inserted to enhance the level and/or tissue-specificity of a promoter.

"Constitutive promoters" refers to those that direct gene expression in all tissues and at all times.

"Organ-specific" or "development-specific" promoters as referred to herein are those that direct gene expression almost exclusively in specific organs, such as leaves or seeds, or at specific development stages in an organ, such as in early or late embryogenesis, respectively.

The term "expression", as used herein, is intended to mean the production of the protein product encoded by a gene. "Overexpression" refers to the production of a

gene product in transgenic organisms that exceeds levels of production in normal or non-transformed organisms.

The "3' non-coding sequences" refers to the DNA sequence portion of a gene that contains a transcription  
5 termination signal, polyadenylation signal, and any other regulatory signal capable of affecting mRNA processing or gene expression. The polyadenylation signal is usually characterized by affecting the addition of polyadenylic acid tracts to the 3' end of  
10 the mRNA precursor.

The "5' non-coding sequences" refers to the DNA sequence portion of a gene that contains a promoter sequence and a translation leader sequence.

The "translation leader sequence" refers to that  
15 DNA sequence portion of a gene between the promoter and coding sequence that is transcribed into RNA and is present in the fully processed mRNA upstream (5') of the translation start codon. The translation leader sequence may affect processing of the primary transcript  
20 to mRNA, mRNA stability or translation efficiency.

"Mature" protein refers to a post-translationally processed polypeptide without its signal peptide.

"Precursor" protein refers to the primary product of translation of mRNA. "Signal peptide" refers to the  
25 amino terminal extension of a polypeptide, which is translated in conjunction with the polypeptide forming a precursor peptide and which is required for its entrance into the secretory pathway. The term "signal sequence" refers to a nucleotide sequence that encodes the signal  
30 peptide.

"Intracellular localization sequence" refers to a nucleotide sequence that encodes an intracellular targeting signal. An "intracellular targeting signal" is an amino acid sequence which is translated in  
35 conjunction with a protein and directs it to a

particular sub-cellular compartment. "Endoplasmic reticulum (ER) stop transit signal" refers to a carboxy-terminal extension of a polypeptide, which is translated in conjunction with the polypeptide and causes a protein  
5 that enters the secretory pathway to be retained in the ER. "ER stop transit sequence" refers to a nucleotide sequence that encodes the ER targeting signal. Other intracellular targeting sequences encode targeting signals active in seeds and/or leaves and vacuolar  
10 targeting signals.

"Transformation" herein refers to the transfer of a foreign gene into the genome of a host organism and its genetically stable inheritance. Examples of methods of plant transformation include Agrobacterium-mediated  
15 transformation and accelerated-particle or "gene gun" transformation technology.

Recombinant DNA technology offers the potential for increasing the sulfur amino acid content of crop plants. Particularly useful technologies are: (a) methods for  
20 the molecular cloning and in vitro manipulation of genes [see Sambrook et al. (1989) Molecular Cloning: a Laboratory Manual, Cold Spring Harbor Laboratory Press], (b) introduction of genes via transformation into agriculturally-important crop plants such as soybean  
25 [Chee et al. (1989) Plant Physiol. 91:1212-1218; Christou et al. (1989) Proc. Nat. Acad. Sci U.S.A. 86:7500-7504; Hinchey et al. (1989) Biotechnology 6:915-922; EPO publication 0301 749 A2], rapeseed [De Block et al. (1989) Plant Physiol. 91:694-701], and corn [Gordon-Kamm et al. (1990) Plant Cell 2:603-618; Fromm et al.  
30 (1990) Biotechnology 8:833-839], and (c) seed-specific expression of introduced genes in transgenic plants [see Goldberg et al. (1989) Cell 56:149-160; Thompson and Larkins (1989) BioEssays 10:108-113]. In order to use  
35 these technologies to develop crop plants with increased

sulfur amino acid content, it is essential to identify and isolate commercially-important genes.

Various solutions used in the experimental manipulations are referred to by their common names such as "SSC", "SSPE", "Denhardt's solution", etc. The composition of these solutions may be found by reference to Appendix B of Sambrook et al., (Molecular Cloning, a Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press).

10

#### Cloning of the Corn HSZ Gene

Based upon the published DNA sequence (SEQ ID NO:5) of the corn 10 kD zein gene [Kirihara et al. (1988) Mol. Gen. Genet. 21:477-484; Kirihara et al. (1988) Gene 71:359-370] oligonucleotides (SEQ ID NOS:6 and 7) were designed for use as primers for polymerase chain reaction (PCR) with genomic corn DNA as template. The product of the PCR reaction was isolated from an agarose gel and radioactively labelled by nick translation for use as a hybridization probe. A corn genomic DNA library in the vector  $\lambda$ -EMBL-3 was purchased from Clontech and plaques were screened with the PCR-generated probe. This was expected to result in the isolation of a full-length 10 kD zein gene including its 5' and 3' regulatory regions.

25

Two hybridizing  $\lambda$  plaques were purified and the cloned corn DNA fragment was further characterized. Restriction endonuclease digests and agarose gel electrophoresis indicated that the two clones were identical. The DNA fragments from the agarose gel were "Southern-blotted" onto nitrocellulose membrane filters and probed with radioactively-labeled 10 kD zein DNA generated by nick translation. A single 7.5kb BamH I fragment and a single 1.4kb Xba I fragment hybridized to

30

the probe. These fragments were subcloned into phagemid pTZ18R (Pharmacia) for DNA sequence analysis.

Surprisingly, from the sequence it was evident that the gene isolated was related to, but distinct from, the 10 kD zein gene. It has been designated the High Sulfur Zein (HSZ) gene. The DNA fragment contains an open reading frame of 633 nucleotides, compared with the 453 nucleotides of the 10 kD zein gene. The HSZ protein shows 76% amino acid sequence identity with the 10 kD zein. However, the longer open reading frame of the HSZ gene codes for a methionine-rich domain not present in the 10 kD zein gene which results in a sulfur amino acid content of 29% (28% methionine) for the mature HSZ protein compared with 26% (22% methionine) for the 10 kD zein. Thus the HSZ gene codes for a seed storage protein which is the highest in methionine of any presently known. Well-known gene expression signals like the TATA box and polyadenylation signal were at similar positions in the HSZ and 10 kD zein genes. A putative 21 amino acid signal sequence is encoded by the HSZ gene at the amino terminus of the precursor polypeptide, similar to that of the 10 kD gene.

The DNA fragment of the instant invention may be used to isolate substantially homologous cDNAs and genes coding for seed storage proteins from corn and other plant species, particularly monocotyledenous plants. Isolation of related genes is well known in the art.

The use of restriction fragment length polymorphism (RFLP) markers in plant breeding has been well-documented in the art [see Tanksley et al. (1989) Bio. Technology 7:257-264]. The nucleic acid fragment of the invention can be mapped on a corn RFLP map. It can thus be used as a RFLP marker for traits linked to the mapped locus.

Modification of the HSZ Gene

The nucleic acid fragment of the instant invention coding for the sulfur-rich seed storage protein may be attached to suitable regulatory sequences and used to  
5 overproduce the protein in microbes such as Escherichia coli or yeast or in transgenic plants such as corn, soybean and other crop plants. Such a recombinant DNA construct may include either the native HSZ gene or a chimeric gene. One skilled in the art can isolate the  
10 coding sequences from the fragment of the invention by using and/or creating restriction endonuclease sites [see Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Laboratory Press].

Of particular utility are naturally occurring sites  
15 for Nco I (5'-CCATGG) and Xba I (5'-TCTAGA) that allow precise removal of the coding sequence starting with the translation initiating codon ATG and ending with the translation stop codon TAG. However, three Nco I sites were present in the HSZ coding region. It was desirable  
20 to eliminate two of these sites and maintain only the one site (nucleotides 751-756 in SEQ ID NO:1) that included the translation start codon. A preferred DNA fragment of the invention (SEQ ID NO:2) was created by in vitro site-directed mutagenesis such that the two Nco  
25 I sites within the coding sequence have been removed without changing the amino acid sequence encoded by the gene. Thus a complete digest of the DNA with Nco I and Xba I yields a unique 637 bp fragment containing the entire coding sequence of the precursor HSZ polypeptide.  
30 To further facilitate the construction of chimeric genes, additional unique restriction endonuclease sites were added immediately following the translation stop signal of HSZ. Oligonucleotides (SEQ ID NOS.:10 and 11) were inserted into the Xba I site, introducing two new  
35 restriction sites, Sma I and Kpn I, and destroying the

Xba I site. The now unique Xba I site from nucleotide 1-6 in SEQ ID NO:1 and the Ssp I site from nucleotide 1823-1828 in SEQ ID NO:1 were used to obtain a fragment that included the HSZ coding region plus its 5' and 3' regulatory regions. This fragment was cloned into the commercially available vector pTZ19R (Pharmacia) digested with Xba I and Sma I, yielding plasmid pCC10. Plasmid pCC10 was deposited on 7 December 1990 at the ATCC, 12301 Parklawn Drive, Rockville, Maryland 20852 under accession number 68490 under the terms of the Budapest Treaty.

In order to be able to express the mature form of the HSZ protein, it was desirable to create an altered form of the HSZ gene with a unique restriction endonuclease site at the start of the mature protein. To accomplish this a DNA fragment was generated using PCR. Oligonucleotide primers (SEQ ID NOS:12 and 13) were designed so that the PCR-generated fragment (SEQ ID NO:3) contained a BspH I site, which results in a cohesive-end identical to that generated by an Nco I digest. This site was located at the junction of the signal sequence and the mature HSZ coding sequence. The PCR-generated fragment also contained an Xba I site at the translation terminus of the HSZ gene.

A gene was constructed using PCR methodology to encode the high methionine domain (HMD) of HSZ. Oligonucleotides (SEQ ID NOS:14 and 15) were designed to add an Nde I site that included the translation initiation codon and an EcoR I site just past the translation termination codon (see SEQ ID NO:4). These sites permit easy insertion of HMD into expression vectors.

Expression of HSZ in E. coli

The HSZ coding sequence was expressed in E. coli using the bacteriophage T7 RNA polymerase/T7 promoter system [Studier et al. (1990) Methods in Enzymology 185:60-89]. The Nco I-Xba I fragment containing the HSZ coding sequence was inserted into an expression vector. This plasmid, designated pCC11, was expected to express the precursor HSZ protein. Additionally, a plasmid designed to express the HSZ protein without its signal sequence, designated pCC12, was constructed. The mature HSZ encoding DNA fragment for this construction was generated using PCR as described above and inserted into the expression vector.

To detect expression of the HSZ polypeptides plasmids pCC11 and pCC12 were transformed into E. coli strain HMS174 and an in vivo labelling experiment using <sup>35</sup>S-methionine was performed as described by Studier and Moffatt [(1986) J. Mol. Biol. 189:113-130]. Because of the high methionine content of the HSZ protein this provides a specific and sensitive means for detection of expression. Cell extracts were run on SDS polyacrylamide gels which were dried and autoradiographed. A prominent labelled protein band of molecular weight about 20 kD was evident in both pCC11 and pCC12 extracts. This is the approximate size expected for the mature length HSZ polypeptide and suggested that the precursor protein made in the pCC11 transformant was being processed by E. coli. When total cell proteins were revealed by Coomassie brilliant blue staining following induction and SDS polyacrylamide gel electrophoresis, a prominent induced 20 kD protein was evident in the pCC12 lysates (but not in pCC11 lysates) indicating high level expression of the mature form of the protein.

The nucleic acid fragments of the invention can be used to produce large quantities of HSZ, HMD, or total protein enriched in sulfur-containing amino acids, particularly methionine, via  
5 fermentation of *E. coli* or other microorganisms. To do this the nucleic acid fragment of the invention can be operably linked to a suitable regulatory sequence comprising a promoter sequence, a translation leader sequence and a 3' noncoding  
10 sequence. The chimeric gene can then be introduced into a microorganism via transformation and the transformed microorganism can be grown under conditions resulting in high expression of the chimeric gene. The cells containing protein  
15 enriched in sulfur-containing amino acids can be collected, and the enriched protein can be extracted. The HSZ protein can then be purified.

To produce large quantities of HSZ protein in *E. coli*, strain BL21(DE3)pLysE [Studier et al. (1990)  
20 Methods in Enzymology 185:60-89] transformed with pCC12 was used. HSZ protein was purified from extracts of IPTG (isopropylthio- $\beta$ -galactoside)-induced cultures. HSZ protein is found in an insoluble precipitate that can be easily collected by low-speed centrifugation of  
25 the cell extract. The majority of the cellular proteins are removed in the supernatant. HSZ is then selectively solubilized in a nearly (>90%) pure form from the centrifugation pellet by extraction with 70% isopropanol containing 10 mM  $\beta$ -mercaptoethanol. Between 10 and 100  
30 mg of HSZ protein was obtained from one liter of cell culture. Because it has now been determined that production of the HSZ protein in *E. coli* is not toxic to the cells, higher levels of expression can be achieved using strain BL21(DE3) [Studier et al. (1990) Methods in  
35 Enzymology 185:60-89].

### Expression of HSZ in Plants

A preferred class of hosts for the expression of the coding sequence of HSZ or HMD are eukaryotic hosts, particularly the cells of higher plants. Particularly preferred among the higher plants and the seeds derived from them are soybean, rapeseed (Brassica napus, B. campestris), sunflower (Helianthus annuus), cotton (Gossypium hirsutum), corn, tobacco (Nicotiana Tubacum), alfalfa (Medicago sativa), wheat (Triticum sp), barley (Hordeum vulgare), oats (Avena sativa, L), sorghum (Sorghum bicolor), rice (Oryza sativa), and forage grasses. Expression in plants will use regulatory sequences functional in such plants.

The expression of foreign genes in plants is well-established [De Blaere et al. (1987) Meth. Enzymol. 153:277-291]. The origin of promoter chosen to drive the expression of the coding sequence is not critical as long as it has sufficient transcriptional activity to accomplish the invention by increasing the level of translatable mRNA for HSZ or HMD in the desired host tissue. Preferred promoters for expression in all plant organs, and especially for expression in leaves include those directing the 19S and 35S transcripts in Cauliflower mosaic virus [Odell et al. (1985) Nature 313:810-812; Hull et al. (1987) Virology 86:482-493], small subunit of ribulose 1,5-bisphosphate carboxylase [Morelli et al. (1985) Nature 315:200; Broglie et al. (1984) Science 224:838; Herrera-Estrella et al. (1984) Nature 310:115; Coruzzi et al. (1984) EMBO J. 3:1671; Faciotti et al. (1985) Bio/Technology 3:241], maize zein protein [Matzke et al. (1984) EMBO J. 3:1525], and chlorophyll a/b binding protein [Lampa et al. (1986) Nature 316:750-752].

Depending upon the application, it may be desirable to select promoters that are specific for expression in one or more organs of the plant. Examples include the light-inducible promoters of the small subunit of ribulose 1,5-bisphosphate carboxylase, if the expression is desired in photosynthetic organs, or promoters active specifically in seeds.

Preferred promoters are those that allow expression of the protein specifically in seeds. This may be especially useful, since seeds are the primary source of vegetable protein and also since seed-specific expression will avoid any potential deleterious effect in non-seed organs. Examples of seed-specific promoters include, but are not limited to, the promoters of seed storage proteins, which represent more than 50% of total seed protein in many plants. The seed storage proteins are strictly regulated, being expressed almost exclusively in seeds in a highly organ-specific and stage-specific manner [Higgins et al. (1984) Ann. Rev. Plant Physiol. 35:191-221; Goldberg et al. (1989) Cell 56:149-160; Thompson et al. (1989) BioEssays 10:108-113]. Moreover, different seed storage proteins may be expressed at different stages of seed development.

There are currently numerous examples for seed-specific expression of seed storage protein genes in transgenic dicotyledonous plants. These include genes from dicotyledonous plants for bean  $\beta$ -phaseolin [Sengupta-Gopalan et al. (1985) Proc. Natl. Acad. Sci. USA 82:3320-3324; Hoffman et al. (1988) Plant Mol. Biol. 11:717-729], bean lectin [Voelker et al. (1987) EMBO J. 6: 3571-3577], soybean lectin [Okamuro et al. (1986) Proc. Natl. Acad. Sci. USA 83:8240-8244], soybean kunitz trypsin inhibitor [Perez-Grau et al. (1989) Plant Cell 1:095-1109], soybean  $\beta$ -conglycinin [Beachy et al. (1985) EMBO J. 4:3047-3053; Barker et al. (1988) Proc. Natl.

Acad. Sci. USA 85:458-462; Chen et al. (1988) EMBO J. 7:297-302; Chen et al. (1989) Dev. Genet. 10:112-122; Naito et al. (1988) Plant Mol. Biol. 11:109-123], pea vicilin [Higgins et al. (1988) Plant Mol. Biol. 11:683-695], pea convicilin [Newbiggin et al. (1990) Planta 180:461], pea legumin [Shirsat et al. (1989) Mol. Gen. Genetics 215:326]; rapeseed napin [Radke et al. (1988) Theor. Appl. Genet. 75:685-694] as well as genes from monocotyledonous plants such as for maize 15 kD zein [Hoffman et al. (1987) EMBO J. 6:3213-3221; Scherthaner et al. (1988) EMBO J. 7:1249-1253; Williamson et al. (1988) Plant Physiol. 88:1002-1007], barley  $\beta$ -hordein [Marris et al. (1988) Plant Mol. Biol. 10:359-366] and wheat glutenin [Colot et al. (1987) EMBO J. 6:3559-3564]. Moreover, promoters of seed-specific genes operably linked to heterologous coding sequences in chimeric gene constructs also maintain their temporal and spatial expression pattern in transgenic plants. Such examples include Arabidopsis thaliana 2S seed storage protein gene promoter to express enkephalin peptides in Arabidopsis and B. napus seeds [Vandekerckhove et al. (1989) Bio/Technology 7:929-932], bean lectin and bean  $\beta$ -phaseolin promoters to express luciferase [Riggs et al. (1989) Plant Sci. 63:47-57], and wheat glutenin promoters to express chloramphenicol acetyl transferase [Colot et al. (1987) EMBO J. 6:3559-3564].

Of particular use in the expression of the nucleic acid fragment of the invention will be the heterologous promoters from several extensively-characterized soybean seed storage protein genes such as those for the Kunitz trypsin inhibitor [Jofuku et al. (1989) Plant Cell 1:1079-1093; Perez-Grau et al. (1989) Plant Cell 1:1095-1109], glycinin [Nielson et al. (1989) Plant Cell 1:313-328],  $\beta$ -conglycinin [Harada et al. (1989) Plant Cell

1:415-425]. Promoters of genes for  $\alpha'$ - and  $\beta$ -subunits of soybean  $\beta$ -conglycinin storage protein will be particularly useful in expressing the HSZ mRNA in the cotyledons at mid- to late-stages of soybean seed development [Beachy et al. (1985) EMBO J. 4:3047-3053; Barker et al. (1988) Proc. Natl. Acad. Sci. USA 85:458-462; Chen et al. (1988) EMBO J. 7:297-302; Chen et al. (1989) Dev. Genet. 10:112-122; Naito et al. (1988) Plant Mol. Biol. 11:109-123] in transgenic plants, since: a) there is very little position effect on their expression in transgenic seeds, and b) the two promoters show different temporal regulation: the promoter for the  $\alpha'$ -subunit gene is expressed a few days before that for the  $\beta$ -subunit gene.

Also of particular use in the expression of the nucleic acid fragments of the invention will be the heterologous promoters from several extensively characterized corn seed storage protein genes such as those from the 10 kD zein [Kirihara et al. (1988) Gene 71:359-370], the 27 kD zein [Prat et al. (1987) Gene 52:51-49; Gallardo et al. (1988) Plant Sci. 54:211-281], and the 19 kD zein [Marks et al. (1985) J. Biol. Chem. 260:16451-16459]. The relative transcriptional activities of these promoters in corn have been reported [Kodrzyck et al. (1989) Plant Cell 1:105-114] providing a basis for choosing a promoter for use in chimeric gene constructs for corn.

Proper level of expression of HSZ or HMD mRNA may require the use of different chimeric genes utilizing different promoters. Such chimeric genes can be transferred into host plants either together in a single expression vector or sequentially using more than one vector.

It is envisioned that the introduction of enhancers or enhancer-like elements into either the native HSZ

promoter or into other promoter constructs will also provide increased levels of primary transcription for HSZ or HMD to accomplish the invention. This would include viral enhancers such as that found in the 35S promoter [Odell et al. (1988) Plant Mol. Biol. 10:263-272], enhancers from the opine genes [Fromm et al. (1989) Plant Cell 1:977-984], or enhancers from any other source that result in increased transcription when placed into a promoter operably linked to the nucleic acid fragment of the invention.

Of particular importance is the DNA sequence element isolated from the gene for the  $\alpha'$ -subunit of  $\beta$ -conglycinin that can confer 40-fold seed-specific enhancement to a constitutive promoter [Chen et al. (1988) EMBO J. 7:297-302; Chen et al. (1989) Dev. Genet. 10:112-122]. One skilled in the art can readily isolate this element and insert it within the promoter region of any gene in order to obtain seed-specific enhanced expression with the promoter in transgenic plants. Insertion of such an element in any seed-specific gene that is expressed at different times than the  $\beta$ -conglycinin gene will result in expression in transgenic plants for a longer period during seed development.

The invention can also be accomplished by a variety of other methods to obtain the desired end. In one form, the invention is based on modifying plants to produce increased levels of HSZ protein by virtue of having significantly larger numbers of copies of the HSZ.

Any 3' non-coding region capable of providing a transcription termination signal, a polyadenylation signal and other regulatory sequences that may be required for the proper expression of the HSZ coding region can be used to accomplish the invention. This

would include the native 3' end of the HSZ gene(s), the 3' end from a heterologous zein gene, the 3' end from any storage protein such as the 3' end of the soybean  $\beta$ -conglycinin gene, the 3' end from viral genes such as the 3' end of the 35S or the 19S cauliflower mosaic virus transcripts, the 3' end from the opine synthesis genes, the 3' ends of ribulose 1,5-bisphosphate carboxylase or chlorophyll a/b binding protein, or 3' end sequences from any source such that the sequence employed provides the necessary regulatory information within its nucleic acid sequence to result in the proper expression of the promoter/HSZ, or the promoter/HMD coding region combination to which it is operably linked. There are numerous examples in the art that teach the usefulness of different 3' non-coding regions [for example, see Ingelbrecht et al. (1989) Plant Cell 1:671-680].

DNA sequences coding for intracellular localization sequences may be added to the HSZ or HMD coding sequence if required for the proper expression of the proteins to accomplish the invention. Thus the native signal sequence of HSZ could be removed or replaced with a signal sequence known to function in the target plant. If the signal sequence were removed, the HSZ protein would be expected to remain in the cytoplasm of the cell. Alternatively, the monocot signal sequence of HSZ could be replaced by the signal sequence from the  $\beta$  subunit of phaseolin from the bean Phaseolus vulgaris, or the signal sequence from the  $\alpha$ ' subunit of  $\beta$ -conglycinin from soybean [Doyle et al. (1986) J. Biol. Chem. 261:9228-9238], which function in dicot plants. Hoffman et al. [(1987) EMBO J. 6:3213-3221] showed that the signal sequence of the monocot precursor of a 15 kD zein directed the protein into the secretory pathway and was also correctly processed in transgenic tobacco

seeds. However, the protein did not remain within the endoplasmic reticulum as is the case in corn. To retain the protein in the endoplasmic reticulum it may be necessary to add stop transit sequences. It is known in the art that the addition of DNA sequences coding for the amino acid sequence [lys-asp-glu-leu] (SEQ ID NO:28) at the carboxyl terminal of the protein retains proteins in the lumen of the endoplasmic reticulum [Munro et al. (1987) Cell 48:899-907; Pelham (1988) EMBO J. 7:913-918; Pelham et al. (1988) EMBO J. 7:1757-1762; Inohara et al. (1989) Proc. Natl. Acad. Sci. U.S.A. 86:3564-3568; Hesse et al. (1989) EMBO J. 8:2453-2461]. In some plants seed storage proteins are located in the vacuoles of the cell. In order to accomplish the invention it may be necessary to direct the HSZ or HMD protein to the vacuole of these plants by adding a vacuolar targeting sequence. A short amino acid domain that serves as a vacuolar targeting sequence has been identified from bean phytohemagglutinin which accumulates in protein storage vacuoles of cotyledons [Tague et al. (1990) Plant Cell 2:533-546]. In another report a carboxyl-terminal amino acid sequence necessary for directing barley lectin to vacuoles in transgenic tobacco was described [Bednarek et al. (1990) Plant Cell 2:1145-1155].

Construction of Chimeric Genes  
for Expression of HSZ in Plants

Three seed-specific gene expression cassettes were used for construction of chimeric genes for expression of HSZ in plants. The expression cassettes contained the regulatory regions from three highly expressed seed storage protein genes:

- 1) the  $\beta$  subunit of phaseolin from the bean Phaseolus vulgaris;

- 2) the  $\alpha'$  subunit of  $\beta$ -conglycinin from soybean; and

- 3) the 10 kD zein from corn.

The cassettes are shown schematically in Figure 2. They  
5 each have a unique Nco I site immediately following the 5' regulatory region and, in addition, some or all of the sites Xba I, Sma I and Kpn I immediately preceding the 3' regulatory region.

The Nco I-Xba I fragment containing the entire HSZ  
10 coding region (SEQ ID NO:2) and the BspH I-Xba I fragment containing the gene without the signal sequence, i.e. the mature protein coding sequence (SEQ ID NO:3), were inserted into the phaseolin and  $\beta$ -conglycinin expression cassettes (Figure 2) which had  
15 been digested with Nco I and Xba I. For insertion into the 10 kD zein cassette, the Nco I-Sma I fragment containing the HSZ coding region was inserted into Nco I-Sma I digested 10 kD zein cassette.

Various methods of transforming cells of higher  
20 plants according to the present invention are available to those skilled in the art (see EPO publications 0 295 959 A2 and 0 138 341 A1). Such methods include those based on transformation vectors based on the Ti and Ri plasmids of Agrobacterium spp. It is  
25 particularly preferred to use the binary type of these vectors. Ti-derived vectors transformed a wide variety of higher plants, including monocotyledonous and dicotyledonous plants, such as soybean, cotton and rape [Pacciotti et al. (1985) Bio/Technology 3:241; Byrne et  
30 al. (1987) Plant Cell, Tissue and Organ Culture 8:3; Sukhapinda et al. (1987) Plant Mol. Biol. 8:209-216; Lorz et al. (1985) Mol. Gen. Genet. 199:178; Potrykus (1985) Mol. Gen. Genet. 199:183].

The phaseolin-HSZ chimeric gene cassettes were  
35 inserted into the vector pZS97K (Figure 3) which is part

of a binary Ti plasmid vector system [Bevan (1984) Nucl. Acids. Res. 12:8711-8720] of Agrobacterium tumefaciens. The vector contains: (1) the chimeric gene nopaline synthase/neomycin phosphotransferase (nos:NPT II) as a  
5 selectable marker for transformed plant cells [Bevan et al. (1983) Nature 304:184-186], (2) the left and right borders of the T-DNA of the Ti plasmid [Bevan (1984) Nucl. Acids. Res. 12:8711-8720], (3) the E. coli lacZ  $\alpha$ -complementing segment [Vieria and Messing (1982) Gene  
10 19:259-267] with unique restriction endonuclease sites for EcoR I, Kpn I, BamH I and Sal I, (4) the bacterial replication origin from the Pseudomonas plasmid pVS1 [Itoh et al. (1984) Plasmid 11:206-220], and 5) the bacterial neomycin phosphotransferase gene from Tn5  
15 [Berg et al. (1975) Proc. Natl. Acad. Sci. U.S.A. 72:3628-3632] as a selectable marker for transformed A. tumefaciens.

The binary vectors containing the chimeric HSZ genes were transferred by tri-parental matings [Ruvkin  
20 et al. (1981) Nature 289:85-88] to Agrobacterium strain LBA4404/pAL4404 [Hockema et al (1983) Nature 303:179-180]. The Agrobacterium transformants were used to inoculate tobacco leaf disks [Horsch et al. (1985) Science 227:1229-1231]. Plants were regenerated in  
25 selective medium containing kanamycin.

Other transformation methods are available to those skilled in the art, such as direct uptake of foreign DNA constructs [see EPO publication 0 295 959 A2], techniques of electroporation [see Fromm et al. (1986)  
30 Nature (London) 319:791] or high-velocity ballistic bombardment with metal particles coated with the nucleic acid constructs [see Kline et al. (1987) Nature (London) 327:70, and see U. S. Pat. No. 4,945,050]. Once transformed the cells can be regenerated by those  
35 skilled in the art.

Of particular relevance are the recently described methods to transform foreign genes into commercially important crops, such as rapeseed [see De Block et al. (1989) Plant Physiol. 91:694-701], sunflower [Everett et al. (1987) Bio/Technology 5:1201], soybean [McCabe et al. (1988) Bio/Technology 6:923; Hinchee et al. (1988) Bio/Technology 6:915; Chee et al. (1989) Plant Physiol. 91:1212-1218; Christou et al. (1989) Proc. Natl. Acad. Sci USA 86:7500-7504; EPO Publication 0 301 749 A2], and corn [Gordon-Kamm et al. (1990) Plant Cell 2:603-618; Fromm et al. (1990) Biotechnology 8:833-839]

### EXAMPLES

The present invention is further defined in the following EXAMPLES, in which all parts and percentages are by weight and degrees are Celsius, unless otherwise stated. It should be understood that these EXAMPLES, while indicating preferred embodiments of the invention, are given by way of illustration only. From the above discussion and these EXAMPLES, one skilled in the art can ascertain the essential characteristics of this invention, and without departing from the spirit and scope thereof, can make various changes and modifications of the invention to adapt it to various usages and conditions.

#### EXAMPLE 1

##### Molecular Cloning of the HSZ Gene

A genomic library of corn in bacteriophage lambda was purchased from Clontech (Palo Alto, California). Data sheets from the supplier indicated that the corn DNA was from seven-day-old seedlings grown in the dark. The vector was  $\lambda$ -EMBL-3 carrying BamHI fragments 15 kb in average size. A titer of 1 to  $9 \times 10^9$  plaque forming units (pfu)/mL was indicated by the supplier. Upon its

arrival the library was titered and contained  $2.5 \times 10^9$  pfu/mL.

The protocol for screening the library by DNA hybridization was provided by the vendor. About 30,000  
5 pfu were plated per 150-mm plate on a total of 15 Luria Broth (LB) agar plates giving 450,000 plaques. Plating was done using *E. coli* LE392 grown in LB + 0.2% maltose as the host and LB-7.2% agarose as the plating medium. The plaques were absorbed onto nitrocellulose filters  
10 (Millipore HATF, 0.45  $\mu$ m pore size), denatured in 1.5 M NaCl, 0.5 M Tris-Cl pH 7.5, and rinsed in 3XSSC [Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Laboratory Press]. The filters were blotted on Whatman 3MM paper and heated in  
15 a vacuum oven at 80°C for two hours to allow firm anchorage of phage DNA in the membranes.

A hybridization probe was generated to screen the library for a high methionine 10 kD zein gene [Kirihara et al. (1988) Mol. Gen. Genet. 211:477-484] along with  
20 its 5' and 3' flanking regions. Two oligonucleotides 30 bases long flanking this gene were synthesized using an Applied Biosystems DNA synthesizer. Oligomer SM56 (SEQ ID NO:6) codes for the positive strand spanning the  
first ten amino acids:

25

SM56 5'-ATG GCA GCC AAG ATG CTT GCA TTG TTC GCT-3' (SEQ ID NO:6)  
Met Ala Ala Lys Met Leu Ala Leu Phe Ala (amino acids  
-21 to -12 of  
SEQ ID NO:5)

30

Oligomer CFC77 (SEQ ID NO:7) codes for the negative strand spanning the last ten amino acids:

CFC77 3'-AAT GTC GTT GGG AAA CAA CCA CGA CGT AAG-5' (SEQ ID NO:7)  
Leu Gln Gln Pro Phe Val Gly Ala Ala Phe (amino acids  
120 to 129 of  
SEQ ID NO:5)

5

These were employed to generate by polymerase chain reaction (PCR) the 10 kD coding region using maize genomic DNA (B85 strain) as the template. PCR was performed using a Perkin-Elmer Cetus kit according to the instructions of the vendor on a thermocycler manufactured by the same company. The reaction product when run on a 1% agarose gel and stained with ethidium bromide showed a strong DNA band of the size expected for the 10 kD zein gene, 450 bp, with a faint band at about 650 bp. The 450 bp band was electro-eluted onto DEAE cellulose membrane (Schleicher & Schuell) and subsequently eluted from the membrane at 65°C with 1 M NaCl, 0.1 mM EDTA, 20 mM Tris-Cl, pH 8.0. The DNA was ethanol precipitated and rinsed with 70% ethanol and dried. The dried pellet was resuspended in 10 µL water, and an aliquot (usually 1 µL) was used for another set of PCR reactions, to generate by asymmetric priming single-stranded linear DNAs. For this, the primers SM56 and CFC77 were present in a 1:20 molar ratio and 20:1 molar ratio. The products, both positive and negative strands of the 10 kD zein gene, were phenol extracted, ethanol precipitated, and passed through NACS (Bethesda Research Laboratories) columns to remove the excess oligomers. The eluates were ethanol precipitated twice, rinsed with 70% ethanol, and dried. DNA sequencing was done using the appropriate complementary primers and a sequenase kit from United States Biochemicals Company according to the vendors instructions. The sequence of the PCR product was identical to the published sequence of the 10 kD zein gene. A radioactive probe was made by

nick-translation of the PCR-generated 10 kD zein gene using  $^{32}\text{P}$ -dCTP and a nick-translation kit purchased from Bethesda Research Laboratories.

5 The fifteen 150-mm nitrocellulose filters carrying the  $\lambda$  phage plaques were screened using radioactive 10 kD gene probe. After four hours prehybridizing at 60°C in 50XSSPE, 5X Denhardt's, [see Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Laboratory Press] 0.1% SDS, 100 g/mL calf  
10 thymus DNA, the filters were transferred to fresh hybridization mix containing the denatured radiolabeled 10 kD zein gene (cpm/mL) and stored overnight at 60°C. They were rinsed the following day under stringent conditions: one hour at room temp in 2XSSC - 0.05% SDS  
15 and one hour at 68°C in 1XSSC - 0.1% SDS. Blotting on 3MM Whatman paper followed, then air drying and autoradiography at -70°C with Kodak XAR-5 films with Du Pont Cronex® Lightning Plus intensifying screens. From these autoradiograms, 20 hybridizing plaques were  
20 identified. These plaques were picked from the original petri plate and plated out at a dilution to yield about 100 plaques per 80-mm plate. These plaques were absorbed to nitrocellulose filters and re-probed using the same procedure. After autoradiography only one of  
25 the original plaques, number 10, showed two hybridizing plaques. These plaques were tested with the probe a third time; all the progeny plaques hybridized, indicating that pure clones had been isolated.

DNA was prepared from these two phage clones,  
30  $\lambda$  10-1,  $\lambda$  10-2, using the protocol for DNA isolation from small-scale liquid  $\lambda$ -phage lysates (Ansul et al. (1987) Current Protocols in Molecular Biology, pp. 1.12.2, 1.13.5-6). Restriction endonuclease digests and agarose gel electrophoresis showed the two clones to be  
35 identical. The DNA fragments from the agarose gel were

"Southern-blotted" [see Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Laboratory Press] onto nitrocellulose membrane filters and probed with radioactively-labeled 10 kD zein DNA  
5 generated by nick translation. A single 7.5 kb BamH I fragment and a single 1.4 kb Xba I fragment hybridized to the probe.

The 7.5 kb BamH I fragment was isolated from a BamH I digest of the  $\lambda$  DNA run on an 0.5% low melting  
10 point (LMP) agarose gel. The 7.5 kb band was excised, melted, and diluted into 0.5 M NaCl and loaded onto a NACS column, which was then washed with 0.5 M NaCl, 10 mM Tris-Cl, pH 7.2, 1 mM EDTA and the fragment eluted  
15 with 2 M NaCl, 10 mM Tris-Cl, pH 7.2, 1 mM EDTA. This fragment was ligated to the phagemid pTZ18R (Pharmacia) which had been cleaved with BamH I and treated with calf intestinal alkaline phosphatase [see Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual, Cold  
20 Spring Harbor Laboratory Press] to prevent ligation of the phagemid to itself. Subclones with these fragments in both orientations with respect to the pTZ18R DNA were obtained following transformation of *E. coli*.

An Xba I digest of the cloned  $\lambda$ phage DNA was run on an 0.8% agarose gel and a 1.4 kb fragment was  
25 isolated using DEAE cellulose membrane (same procedure as for the PCR-generated 10 kD zein DNA fragment described above). This fragment was ligated to pTZ18R cut with Xba I in the same way as described above. Subclones with these fragments in both orientations with  
30 respect to the pTZ18R DNA, designated pX8 and pX10, were obtained following transformation of *E. coli*. Single-stranded DNAs were made from the subclones using the protocol provided by Pharmacia. The entire 1.4 kb Xba I fragments were sequenced. An additional 700 bases  
35 adjacent to the Xba I fragment was sequenced from the

BamH I fragment in clone pB3 (fragment pB3 is in the same orientation as pX8) giving a total of 2123 bases of sequence (SEQ ID NO:1).

#### EXAMPLE 2

##### 5                    Modification of the HSZ Gene by                     Site-Directed Mutagenesis

Three Nco I sites were present in the 1.4 kD Xba I fragment carrying the HSZ gene, all in the HSZ coding region. It was desirable to maintain only one of these  
10 sites (nucleotides 751-756 in SEQ ID NO:1) that included the translation start codon. Therefore, the Nco I sites at positions 870-875 and 1333-1338 were eliminated by oligonucleotide-directed site-specific mutagenesis [see  
15 Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Laboratory Press]. The oligonucleotides synthesized for the mutagenesis were:

CFC99            ATGAACCCTT GGATGCA        (SEQ ID NO:8)

20 CFC98           CCCACAGCAA TGGCGAT        (SEQ ID NO:9)

Mutagenesis was carried out using a kit purchased from Bio-Rad (Richmond, CA), following the protocol provided by the vendor.

25            The process changed the A to T at 872 and the C to A at 1334. These were both at the third position of their respective codons and resulted in no change in the amino acid sequence encoded by the gene, with C C A to C C T, still coding for Pro and G C C to G C A, still  
30 coding for Ala. The plasmid clone containing the modified HSZ gene with a single Nco I site at the ATG start codon was designated pX8m. Because the native HSZ gene has a unique Xba I site at the stop codon of the gene (1384-1389, SEQ ID NO:1), a complete digest of the  
35 DNA with Nco I and Xba I yields a 637 bp fragment

containing the entire coding sequence of the precursor HSZ polypeptide (SEQ ID NO:2).

It was desirable to create a form of the HSZ gene with alternative unique restriction endonuclease sites just past the end of the coding region. To do this oligonucleotides CFC104 (SEQ ID NO:10) and CFC105 (SEQ ID NO:11):

CFC104      5'-CTAGCCCGGGTAC      -3'      (SEQ ID NO:10)  
10 CFC105      3'-      GGGCCCATGGATC-5'      (SEQ ID NO:11)

were annealed and ligated into the Xba I site, introducing two new restriction sites, Sma I and Kpn I, and destroying the Xba I site. The now unique Xba I site from nucleotide 1-6 in SEQ ID NO:1 and the Ssp I site from nucleotide 1823-1828 in SEQ ID NO:1 were used to obtain a fragment that included the HSZ coding region plus its 5' and 3' regulatory regions. This fragment was cloned into the commercially-available vector pTZ19R (Pharmacia) digested with Xba I and Sma I, yielding plasmid pCC10.

It was desirable to create an altered form of the HSZ gene with a unique restriction endonuclease site at the start of the mature protein, i.e. with the amino terminal signal sequence removed. To accomplish this a DNA fragment was generated using PCR as described in EXAMPLE 1. Template DNA for the PCR reaction was plasmid pX8m. Oligonucleotide primers for the reaction were:

30 CFC106      5'-CCACTTTCATGACCCATATCCCAGGGCACTT-3'      (SEQ ID NO:12)  
  
CFC88      5'-TTCTATCTAGAATGCAGCACCAACAAAGGG-3'      (SEQ ID NO:13)

The CFC106 (SEQ ID NO:12) oligonucleotide provided the PCR-generated fragment with a BspH I site (underlined), which when digested with BspH I results in a cohesive-end identical to that generated by an Nco I digest.

5 This site was located at the junction of the signal sequence and the mature HSZ coding sequence. The CFC88 (SEQ ID NO:13) oligonucleotide provided the PCR-generated fragment with an Xba I site (underlined) at the translation terminus of the HSZ gene. The BspH  
10 I-Xba I fragment (SEQ ID NO:3) obtained by digestion of the PCR-generated fragment, encodes the mature form of HSZ with the addition of a methionine residue at the amino terminus of the protein to permit initiation of translation.

15

### EXAMPLE 3

#### Expression of the HSZ Gene in E. coli

To express the HSZ coding sequence in E. coli the bacterial expression vector pBT430 was used. This vector is a derivative of pET-3a [Rosenberg et al.  
20 (1987) Gene 56:125-135] which employs the bacteriophage T7 RNA polymerase/T7 promoter system. Plasmid pBT430 was constructed by first destroying the EcoR I and Hind III sites in pET-3a at their original positions. An oligonucleotide adaptor containing EcoR I and  
25 Hind III sites was then inserted at the BamH I site of pET3a. This created pET-3aM with additional unique cloning sites for insertion of genes into the expression vector. Then, the Nde I site at the position of translation initiation was converted to an Nco I site  
30 using oligonucleotide-directed mutagenesis. The DNA sequence of pET-3aM in this region, 5'-CATATGG (Nde I site underlined), was converted to 5'-CCCATGG (Nco I site underlined) in pBT430.

The Nco I-Xba I fragment of pX8m (SEQ ID NO:2, see  
35 Example 2) was isolated from an agarose gel following

electrophoresis using DEAE cellulose membrane as described in Example 1. This fragment was ligated to two annealed oligonucleotides, CFC104 (SEQ ID NO:10) and CFC105 (SEQ ID NO:11)

5

CFC104      5'-CTAGCCCGGGTAC      -3' (SEQ ID NO:10)

CFC105      3'-      GGGCCCATGGATC-5' (SEQ ID NO:11)

10      introducing two new restriction sites, Sma I and Kpn I at the Xba I end of the fragment. Ligation was terminated by heating at 65°C for 10 minutes. The ligation products were digested Sma I, leaving a 3' blunt-ended fragment. Expression vector pBT430 was digested with EcoR I and the cohesive ends were filled  
15      in by addition of dATP, dTTP and the Klenow fragment of *E. coli* DNA polymerase. The blunt-ended vector DNA was then digested with Nco I and the reaction mixture was phenol-extracted and ethanol-precipitated twice. The  
20      640 bp Nco I-Sma I fragment containing the HSZ coding region was ligated to the Nco I-blunt pBT430 vector. A clone containing a plasmid designated pCC11 was identified by screening *E. coli* transformants for the desired recombinant product. This plasmid was expected to express the precursor HSZ protein.

25

    A plasmid designed to express the HSZ protein without its signal sequence in *E. coli* was also constructed. The mature HSZ encoding DNA fragment for this construction was generated using PCR with plasmid pX8m as template and oligonucleotides CFC106 (SEQ ID  
30      NO:12) and CFC88 (SEQ ID NO:13) as primers as described in Example 2:

CFC106      5'-CCACTTCATGACCCATATCCCAGGGCACTT-3'      (SEQ ID NO:12)  
MetThrHisIleProGlyHisLeu      (amino acids  
1 to 8 of  
SEQ ID NO:3)

5

CFC88      3'-GGGAAACAACCACGACGTAAGATCTATCTT-5'      (SEQ ID NO:13)  
ProPheValGlyAlaAlaPheEnd      (amino acids  
185 to 191 of  
SEQ ID NO:3)

10

The CFC106 (SEQ ID NO:12) oligonucleotide provided the PCR fragment with a BspH I site (underlined above) which generates cohesive ends identical to Nco I. The ATG sequence within the site is the translation initiation codon, and the ACC sequence following it codes for the threonine residue at the amino terminus of the mature protein. The Xba I site in the CFC88 (SEQ ID NO:13) oligonucleotide (underlined above) provided a convenient cloning site at the end of the coding sequence. The PCR reaction product was precipitated in 2 M ammonium acetate, 70% ethanol two times to remove excess oligonucleotide primers. The ends of the DNA fragment were made blunt by reaction with the Klenow fragment of *E. coli* DNA polymerase in the presence of all four deoxyribonucleotide triphosphates. The reaction products were separated by agarose gel electrophoresis and stained with ethidium bromide. The predominant 570 bp band was eluted using DEAE cellulose membrane as describe above. The DNA was then digested with BspH I, twice ethanol precipitated, and ligated to the same Nco I-blunt pBT430 expression vector fragment described above. A clone containing a plasmid designated pCC12 was identified by screening *E. coli* transformants for the desired recombinant product. The cloned PCR-

15

20

25

30

generated fragment was sequenced; the sequence was identical to SEQ ID NO:3.

To detect expression of the HSZ polypeptides plasmids pCC11 and pCC12 were transformed into *E. coli* strain HMS174 and an *in vivo* labelling experiment was performed as described by Studier and Moffatt (1986) J. Mol. Biol. 189:113-130. Proteins were labelled one hour after induction (by infection with  $\lambda$  phage CE6 carrying the T7 RNA polymerase gene) with  $^{35}\text{S}$ -methionine, which was expected to very prominently label these methionine-rich polypeptides. Cell extracts were run on SDS polyacrylamide gels which were dried and autoradiographed. A prominent band of molecular weight about 20 kD was evident in both pCC11 and pCC12 extracts. This is the approximate size expected for the mature length HSZ polypeptide and suggested that the precursor protein made in the pCC11 transformant was being processed by *E. coli*. When total cell proteins were revealed by Coomassie brilliant blue staining following induction and SDS polyacrylamide gel electrophoresis, a prominent induced 20 kD protein was evident in the pCC12 lysates, but not in the pCC11 lysates.

#### EXAMPLE 4

##### Purification of the HSZ protein produced in *E. coli*

A 1-L culture of *E. coli* strain BL21(DE3)pLyse [Studier et al. (1990) Methods in Enzymology 185:60-89] transformed with pCC12 was grown in LB medium containing ampicillin (100 mg/L) and chloramphenicol (10 mg/L) at 37°C. At an optical density at 600 nm of 1.08, 1.2 mL of 0.1 M IPTG (isopropylthio- $\beta$ -galactoside, the inducer) was added and incubation was continued for 3 h at 37°C. The cells were collected by centrifugation, washed with 50 mM NaCl; 50 mM Tris-Cl, pH 7.5; 1 mM EDTA, resuspended with 10 mL of the same buffer, and frozen at -20°C.

The suspension was thawed and Triton X-100 was added to a concentration of 0.1%, followed by 3000 units of deoxyribonuclease I (Boehringer-Mannheim). After incubation at room temperature for 60 minutes the suspension was sonicated on ice to reduce viscosity. The mixture was centrifuged and the supernatant was discarded. The pellet was extracted twice with 5 mL of 70% isopropanol; 10 mM  $\beta$ -mercaptoethanol. HSZ, unlike most proteins, is soluble in this solvent. SDS polyacrylamide gel electrophoresis and Coomassie brilliant blue staining revealed that the HSZ protein was the major protein of the first extraction (>90%) and the only evident protein in the second extraction. Between 10 and 100 mg of HSZ protein were obtained from 1 L of cell culture. Purified HSZ protein was sent to Hazelton Research Facility, 310 Swampridge Road, Denver, PA 17517 to have rabbit antibodies raised against the protein.

#### EXAMPLE 5

##### Construction of a Gene Encoding the High Methionine Domains of HSZ

The HSZ protein is composed of a central very-methionine-rich region (approximately 48% methionine residues) flanked by amino terminal and carboxy terminal regions with lower methionine content (10% methionine and 7% methionine, respectively). The central region is composed of the repeating motif Met-Met-Met-Pro (SEQ ID NO:27). The related 10 kD zein protein has a similar structure (see Figure 3). However, the central region of the HSZ protein is about twice as large as the corresponding region in the 10 kD zein, accounting for the increased methionine content of HSZ. The apparent duplication of the central high methionine domain in HSZ compared to 10 kD zein suggested that the central high methionine domain might have a stable structure and

could be expressed by itself, yielding a very high methionine storage protein.

A gene was constructed to encode the high methionine domain (HMD) of HSZ. To accomplish this PCR was used as described in Example 1 with pX8 as the template DNA and the oligonucleotides JR5 (SEQ ID NO:14) and JR6 (SEQ ID NO:15) as primers for the DNA synthesis:

JR5 5'-TCACCGCTTCAGCAGTGCCCATATGCCAATG-3' (SEQ ID NO:14)

JR6 5'-TCTTAGAATTCTATGGCATCATCATTGGTGACACCATGCT-3' (SEQ ID NO:15)

Primer JR5 (SEQ ID NO:14) causes the addition of an Nde I site (underlined above) in the PCR product.

Primer JR6 (SEQ ID NO:15) adds an EcoR I site (underlined above) in the PCR product. These sites permit ligation of the HMD to the pET-3aM expression vector [Rosenberg et al. (1987) Gene 56:125-135 and Example 3]. The ATG nucleotides of the Nde I site is the translation initiation codon in the expression vector and the EcoR I site immediately follows the translation termination codon.

The PCR product was digested with Nde I and EcoR I and ligated to pET-3aM which had been digested with Nde I and EcoR I. Following transformation of *E. coli*, clones containing the desired recombinant plasmid were identified and verified by DNA sequencing of the inserted DNA fragment. The nucleotide and derived amino acid sequence of the HMD gene is shown in SEQ ID NO:4.

#### EXAMPLE 6

#### Construction of Chimeric Genes for Expression of HSZ in Plants

Three seed-specific gene expression cassettes were used for construction of chimeric genes for expression of HSZ in plants. The expression cassettes contained

the regulatory regions from three highly expressed seed storage protein genes:

- 1) the  $\beta$  subunit of phaseolin from the bean *Phaseolus vulgaris*;
- 5        2) the  $\alpha'$  subunit of  $\beta$ -conglycinin from soybean; and
- 3) the 10 kD zein from corn.

The cassettes are shown schematically in Figure 2.

The phaseolin cassette includes about 500  
10 nucleotides upstream (5') from the translation initiation codon and about 1650 nucleotides downstream (3') from the translation stop codon of phaseolin. Between the 5' and 3' regions are the unique restriction endonuclease sites Nco I (which includes the ATG  
15 translation initiation codon), Sma I, Kpn I and Xba I. The entire cassette is flanked by Hind III sites. The DNA sequence of these regulatory regions have been described in the literature [Doyle et al. (1986) J. Biol. Chem. 261:9228-9238]. Recent work by Bustos et  
20 al. [(1991) EMBO J. 10:1469-1479] indicates that the promoter region of this cassette does not include all of the DNA sequence elements required for the full expression level of the phaseolin promoter, but rather 20-30% of the full expression level would be expected.

25        The  $\beta$ -conglycinin cassette includes about 610 nucleotides upstream (5') from the translation initiation codon of  $\beta$ -conglycinin and about 1650 nucleotides downstream (3') from the translation stop codon of phaseolin. Between the 5' and 3' regions are  
30 the unique restriction endonuclease sites Nco I (which includes the ATG translation initiation codon), Sma I, Kpn I and Xba I. The entire cassette is flanked by Hind III sites. The DNA sequence of these regulatory regions have been described in the literature [Doyle et  
35 al. (1986) J. Biol. Chem. 261:9228-9238].

The 10 kD zein cassette includes about 925 nucleotides upstream (5') from the translation initiation codon and about 945 nucleotides downstream (3') from the translation stop codon of phaseolin.

5 Between the 5' and 3' regions are the unique restriction endonuclease sites Nco I (which includes the ATG translation initiation codon) and Sma I. The entire cassette is flanked by an EcoR I site at the 5' end and BamH I, Sal I and Hind III sites at the 3' end. The DNA  
10 sequence of these regulatory regions have been described in the literature [Kirihara et al. (1988) Gene 71:359-370].

The Nco I-Xba I fragment containing the entire HSZ coding region (see Example 2) was isolated from an  
15 agarose gel following electrophoresis using DEAE cellulose membrane as described in Example 1. The BspH I-Xba I fragment containing the gene without the signal sequence, i.e. the mature protein coding sequence, was isolated as described in Example 3. These  
20 DNA fragments were inserted into the phaseolin and  $\beta$ -conglycinin expression cassettes which had been digested with Nco I-Xba I. Thus four chimeric genes were created:

- 1) phaseolin 5' region/native HSZ/phaseolin 3' region
- 25 2) phaseolin 5' region/mature HSZ/phaseolin 3' region
- 3)  $\beta$ -conglycinin 5' region/native HSZ/phaseolin 3' region
- 4)  $\beta$ -conglycinin 5' region/mature HSZ/phaseolin 3' region.

30 Additional chimeric genes were constructed to replace the native monocot signal sequence of HSZ with a dicot signal sequence from phaseolin. To do this oligonucleotides CFC 112 (SEQ ID NO:16) and CFC 113 (SEQ ID NO:17) were synthesized. The annealed

oligonucleotides form an Nco I compatible end and an Nhe I/Spe I compatible end (see below).

CFC112 5'-CATGATGAGAGCAAGGGTTCCACTCCTGTTGCTGGGAATTCTT  
 5 CFC113 3' TACTCTCGTTCCCAAGGTGAGGACAACGACCCTTAAGAA  
 MetMetArgAlaArgValProLeuLeuLeuLeuGlyIleLeu  
 CFC112 TTCCTGGCATCACTTTCTGCTAGCTTTG 3' (SEQ ID NO:16)  
 CFC113 AAGGACCGTAGTGAAAGACGATCGAAACGATC-5' (SEQ ID NO:17)  
 10 PheLeuAlaSerLeuSerAlaSerPhe (SEQ ID NO:16)

A plasmid, pCC13, containing the HSZ gene flanked by the phaseolin 5' and 3' regulatory regions was digested with Nco I and Spe I, removing most of the  
 15 native signal sequence of HSZ. The annealed oligonucleotides, CFC112 (SEQ ID NO:16) and CFC113 (SEQ ID NO:17), were ligated to the digested pCC13. This plasmid thus created was designated pCC18 and the sequence of the chimeric gene containing the mature HSZ  
 20 protein fused to the phaseolin signal sequence was confirmed by DNA sequencing (SEQ ID NO:18).

Because the Spe I site (nucleotides 57-62 in Seq ID NO:2) was not at the precise junction of the HSZ signal sequence/mature protein, two extra amino acids were  
 25 added between the end of the phaseolin signal sequence and the mature HSZ protein by this procedure. In order to remove these an HSZ fragment was generated via PCR using the oligonucleotides CFC114 (SEQ ID NO:19, see below) and CFC 88 (SEQ ID NO:13, see EXAMPLE 2) serving  
 30 as primers and with pCC18 as the DNA template.

CFC114  
 TTCTGCTAGC TTTGCTACCC ATATCCCAGG G (SEQ ID NO:19)

The PCR product was digested with Nhe I and Xba I and purified by gel electrophoresis. The plasmid pCC18 was digested with the same enzymes to remove the DNA fragment coding for the fusion protein containing the two extra amino acids and the PCR-generated DNA fragment was then inserted. The structure of the resultant plasmid, designated pCC24, was confirmed by DNA sequencing (SEQ ID NO:20).

In order to replace the native signal sequence of HSZ with the phaseolin signal sequence in the chimeric gene that contained the  $\beta$ -conglycinin 5' region, a PCR-generated fragment was synthesized using CFC123 (SEQ ID NO:21, see below) and CFC88 (SEQ ID NO:13, see EXAMPLE 2) as primers and pCC24 as template.

CFC123

ACTAATCATG ATGAGAGCAA GGGTTCCACT (SEQ ID NO:21)

The PCR-generated DNA fragment was digested with BspH I and Xba I and purified by gel electrophoresis. This DNA fragment was inserted into the  $\beta$ -conglycinin expression cassette which had been digested with Nco I-Xba I and the structure of the inserted fragment was confirmed by DNA sequencing (SEQ ID NO:20). This plasmid was designated pCC30.

The oligonucleotides CFC104 (SEQ ID NO:10) and CFC105 (SEQ ID NO:11) (see Example 3) were inserted into the 10 kD zein cassette at the Xba I site at the carboxy terminus adding a unique Sma I site. The Nco I-Sma I fragment containing the HSZ coding region was isolated from plasmid pCC10 (see Example 2) and inserted into Nco I-Sma I digested 10 kD zein cassette.

EXAMPLE 7Transformation of Tobacco with the  
Phaseolin-HSZ Chimeric Genes

The phaseolin-HSZ chimeric gene cassettes,  
5 phaseolin 5' region/native HSZ/phaseolin 3' region, and  
phaseolin 5' region/mature HSZ/phaseolin 3' region  
(Example 6) were isolated as approximately 2.3 kb  
Hind III fragments. Hind III-BamH I adaptor  
oligonucleotides were added to these fragments for  
10 insertion into the unique BamH I site of the vector  
pZS97K (Figure 3) which is part of a binary Ti plasmid  
vector system [Bevan, (1984) Nucl. Acids. Res. 12:8711-  
8720] of Agrobacterium tumefaciens. The vector  
contains: (1) the chimeric gene nopaline  
15 synthase/neomycin phosphotransferase (nos:NPT II) as a  
selectable marker for transformed plant cells [Bevan et  
al. (1983) Nature 304:184-186], (2) the left and right  
borders of the T-DNA of the Ti plasmid [Bevan (1984)  
Nucl. Acids. Res. 12:8711-8720], (3) the E. coli lacZ  
20  $\alpha$ -complementing segment [Vieria and Messing (1982) Gene  
19:259-267] with unique restriction endonuclease sites  
for EcoR I, Kpn I, BamH I and Sal I, (4) the bacterial  
replication origin from the Pseudomonas plasmid pVS1  
[Itoh et al. (1984) Plasmid 11:206-220], and (5) the  
25 bacterial neomycin phosphotransferase gene from Tn5  
[Berg et al. (1975) Proc. Natl. Acad Sci. U.S.A.  
72:3628-3632] as a selectable marker for transformed A.  
tumefaciens.

The phaseolin-HSZ chimeric gene cassette, phaseolin  
30 5' region/phaseolin signal sequence/mature HSZ/phaseolin  
3' region, (Example 6) was isolated as an approximately  
2.3 kb Hind III fragment. This fragment was inserted  
into the unique Hind III site of the binary vector pZS97  
(Figure 4). This vector is similar to pZS97K described  
35 above except for the presence of two additional unique

cloning sites, Sma I and Hind III, and the bacterial  $\beta$ -lactamase gene (causing ampicillin resistance) as a selectable marker for transformed *A. tumefaciens* instead of the bacterial neomycin phosphotransferase gene.

5       The binary vectors containing the chimeric HSZ genes were transferred by tri-parental matings [Ruvkin et al. (1981) Nature 289:85-88] to *Agrobacterium* strain LBA4404/pAL4404 [Hockema et al. (1983) Nature 303:179-180]. The *Agrobacterium* transformants were used to  
10       inoculate tobacco leaf disks [Horsch et al. (1985) Science 227:1229-1231]. Transgenic plants were regenerated in selective medium containing kanamycin.

Genomic DNA was extracted from young leaves and analyzed using PCR to detect the presence of the  
15       chimeric HSZ genes in the transformed tobacco. The oligonucleotides CFC93 (SEQ ID NO:22, see below) and CFC77 (SEQ ID NO:7, see EXAMPLE 1) were used as primers for the PCR reaction.

20       CFC93  
GAATGCAGCA CCAACAAAGG GTTGCTGTAA       (SEQ ID NO:22)

These primers would be expected to generate a 425 bp DNA fragment internal to the HSZ gene. Sixteen of twenty  
25       transformants tested were positive in this assay (see Tables 1 and 2).

To assay for expression of the chimeric genes the transformed plants were allowed to flower, self-pollinate and go to seed. Total proteins were extracted  
30       from mature seeds as follows. Approximately 200 mg of seeds were put into a 1.5 mL disposable plastic microfuge tube and ground in 0.25 mL of 50 mM Tris-Cl pH 6.8, 2 mM EDTA, 1% SDS, 1%  $\beta$ -mercaptoethanol. The grinding was done using a motorized grinder with  
35       disposable plastic shafts designed to fit into the

microfuge tube. The resultant suspensions were centrifuged for 5 minutes at room temperature in a microfuge to remove particulates. Total protein contents of the supernatants were assayed using the  
5 BioRad protein assay with bovine serum albumin as a standard.

From each extract 10  $\mu$ g of protein was run per lane on an SDS polyacrylamide gel, with bacterially produced mature HSZ serving as a positive control and protein  
10 extracted from untransformed tobacco seeds serving as a negative control. The proteins were then electrophoretically blotted onto a nitrocellulose membrane. The membranes were exposed to HSZ antibodies (see EXAMPLE 4) at a 1:700 dilution of the rabbit serum  
15 using standard protocol provided by BioRad with their Immun-Blot Kit. Following rinsing to remove unbound primary antibody the membranes were exposed to the secondary antibody, donkey anti-rabbit Ig conjugated to horseradish peroxidase (Amersham) at a 1:3000 dilution.  
20 Following rinsing to remove unbound secondary antibody the membranes were exposed to Amersham chemiluminescence reagent and X-ray film.

Most of the transformants that contained the HSZ gene based on the PCR analysis also produced HSZ protein  
25 based on the immunological screening (Tables 1-3). In all cases the size of the protein produced was approximately equal to mature HSZ produced in *E. coli*, indicating that both the native and the phaseolin signal sequence had been removed, and thus suggesting that the  
30 protein had entered the endoplasmic reticulum.

Seeds were also extracted with 70% isopropanol/1%  $\beta$ -mercaptoethanol, a solvent in which few proteins other than HSZ are soluble. The proteins were then subjected to SDS-PAGE, Western blotting, and immunological probing  
35 as described above. Under these conditions a protein

the size of mature HSZ was again observed, confirming the identity of the detected proteins as HSZ.

The level of expression of HSZ in the transformed lines was estimated based on the sensitivity of the HSZ  
5 antibody and the amount of protein loaded on the SDS-PAGE gel. HSZ ranged from about 0.05-0.5% of the total seed protein.

To measure the amino acid composition of the seeds,  
6 seeds were hydrolyzed in 6 N hydrochloric acid, 0.4%  
10  $\beta$ -mercaptoethanol under nitrogen for 24 hours at 110-120°C; 1/10 of the sample was run on a Beckman Model 6300 amino acid analyzer using post-column ninhydrin detection. Relative methionine levels in the seeds were compared as a methionine:leucine ratio, thus using  
15 leucine as an internal standard. There was about a 6% standard deviation in the methionine:leucine ratio. At the highest level of expression of HSZ determined by the Western blot analysis, HSZ would be expected to increase the level of methionine in the seed by about 10%.  
20 Because this was so close to the standard deviation, no effect of the expression of HSZ on the total seed methionine was observed (Tables 1-3).

EXAMPLE 8Expression of the HMD protein in E. coli

A culture of *E. coli* strain BL21(DE3)pLysE [Studier  
5 et al. (1990) Methods in Enzymology 185:60-89]  
transformed with plasmid pX8M-18 was grown in 10 L LB  
medium containing ampicillin (100 mg/L) at 37°C. At an  
optical density at 600 nm of about 1, IPTG  
(isopropylthio- $\beta$ -galactoside, the inducer) was added to  
10 a final concentration of 1 mM and incubation was  
continued for 8 h at 37°C. The cells were collected by  
centrifugation, washed with 50 mM NaCl, 50 mM Tris-Cl,  
(pH 7.5), 1 mM EDTA (buffer A), and frozen at -80°C.

The frozen cells were thawed on ice in 5 mL of  
15 buffer A/gram cells. Deoxyribonuclease I (Sigma) was  
added to a concentration of 0.1 mg/mL. After incubation  
at room temperature for 60 minutes the suspension was  
sonicated on ice to reduce viscosity. The mixture was  
centrifuged and the supernatant was discarded. The  
20 pellet was extracted twice with 25 mL of 70%  
isopropanol, 10 mM  $\beta$ -mercaptoethanol. HMD, like HSZ, is  
soluble in this solvent. SDS polyacrylamide gel  
electrophoresis and Coomassie brilliant blue staining  
revealed that the HMD protein was the major protein of  
25 the extraction. Western blot analysis demonstrated that  
HMD protein cross-reacted with rabbit antibody raised to  
HSZ.

EXAMPLE 9Transformation of Tobacco with the30  $\beta$ -conglycinin-HSZ Chimeric Genes

The  $\beta$ -conglycinin chimeric gene cassettes,  
 $\beta$ -conglycinin 5' region/native HSZ/phaseolin 3' region,  
 $\beta$ -conglycinin 5' region/mature HSZ/phaseolin 3' region,  
and  $\beta$ -conglycinin 5' region/phaseolin signal sequence/  
35 mature HSZ/phaseolin 3' region (Example 6) were isolated

as approximately 2.4 kb Hind III fragments. These fragments were inserted into the unique Hind III site of the binary vector pZS97 (Figure 4). This vector is similar to pZS97K described in EXAMPLE 7 except for the presence of two additional unique cloning sites, Sma I and Hind III, and the bacterial  $\beta$ -lactamase gene (causing ampicillin resistance) as a selectable marker for transformed *A. tumefaciens* instead of the bacterial neomycin phosphotransferase gene.

10 The binary vectors containing the chimeric HSZ genes were transferred by tri-parental matings [Ruvkin et al. (1981) Nature 289:85-88] to *Agrobacterium* strain LBA4404/pAL4404 [Hockema et al (1983), Nature 303:179-180]. The *Agrobacterium* transformants were used to inoculate tobacco leaf disks [Horsch et al. (1985) Science 227:1229-1231]. Transgenic plants were regenerated in selective medium containing kanamycin.

To assay for expression of the chimeric genes the transformed plants were allowed to flower, self-pollinate and go to seed. Total proteins were extracted from mature seeds as follows. Approximately 200 mg of seeds were put into a 1.5 mL disposable plastic microfuge tube and ground in 0.25 mL of 50 mM Tris-Cl pH 6.8, 2 mM EDTA, 1% SDS, 1%  $\beta$ -mercaptoethanol. The grinding was done using a motorized grinder with disposable plastic shafts designed to fit into the microfuge tube. The resultant suspensions were centrifuged for 5 minutes at room temperature in a microfuge to remove particulates. Total protein contents of the supernatants were assayed using the BioRad protein assay with bovine serum albumin as a standard.

From each extract 10  $\mu$ g of protein was run per lane on an SDS polyacrylamide gel, with bacterially produced mature HSZ serving as a positive control and protein

extracted from untransformed tobacco seeds serving as a negative control. The proteins were then electrophoretically blotted onto a nitrocellulose membrane. The membranes were exposed to HSZ antibodies (see EXAMPLE 4) at a 1:700 dilution of the rabbit serum using standard protocol provided by BioRad with their Immun-Blot Kit. Following rinsing to remove unbound primary antibody the membranes were exposed to the secondary antibody, donkey anti-rabbit Ig conjugated to horseradish peroxidase (Amersham) at a 1:3000 dilution. Following rinsing to remove unbound secondary antibody the membranes were exposed to Amersham chemiluminescence reagent and X-ray film.

One transformant containing the chimeric gene  $\beta$ -conglycinin 5' region/mature HSZ/phaseolin 3' region and two transformants containing the chimeric gene  $\beta$ -conglycinin 5' region/native HSZ/phaseolin 3' region each produced HSZ protein. Four of seven transformants containing the chimeric gene  $\beta$ -conglycinin 5' region/phaseolin signal sequence-mature HSZ/phaseolin 3' region produced HSZ protein (Table 4). In all cases the size of the protein produced was approximately equal to mature HSZ produced in *E. coli*, indicating that both the native and the phaseolin signal sequence had been removed, and thus suggesting that the protein had entered the endoplasmic reticulum.

To measure the amino acid composition of the seeds, 6 seeds were hydrolyzed in 6N hydrochloric acid, 0.4%  $\beta$ -mercaptoethanol under nitrogen for 24 hours at 110-120°C; 1/10 of the sample was run on a Beckman Model 6300 amino acid analyzer using post-column ninhydrin detection. Relative methionine levels in the seeds were compared as a methionine:leucine ratio, thus using leucine as an internal standard. There was about a 5% standard deviation in the methionine:leucine ratio. The

line with the highest level of HSZ expression based on the Western blot analysis had the highest total seed methionine observed (Table 4), but this was only about 7% above the mean. While this is too close to the error in the measurement to be certain, it is likely that this high methionine level is due to the expression of HSZ.

#### EXAMPLE 10

#### Construction of Chimeric Gene for Expression of HMD in Plants

As in EXAMPLE 6, a seed-specific gene expression cassette was used for construction of a chimeric gene for expression of HMD in plants. The expression cassette contained the regulatory region from the  $\beta$ -subunit of phaseolin from the bean Phaseolus vulgaris. The chimeric gene created also contained a dicot signal sequence from phaseolin: phaseolin 5' region/phaseolin signal sequence/HMD/phaseolin 3' region

PCR primers, CLM 1 (SEQ ID NO:23) and CLM 2 (SEQ ID NO:24) (see below) were synthesized and used with the plasmid pJRHMD1 as template to generate a DNA fragment

containing the HMD sequence fused to the 3' end of the phaseolin signal sequence and flanked by *NheI* and *XbaI* sites. The plasmid pCC24, discussed in EXAMPLE 6, was digested with *NheI*, which cuts within the phaseolin signal sequence, and *XbaI* and purified by agarose gel electrophoresis. The purified vector was ligated to the PCR product formed from CLM 1 (SEQ ID NO:23), CLM 2 (SEQ ID NO:24) and pJRHMD1, thus regenerating the complete phaseolin signal sequence linked to HMD. The ligation product was designated pJRHMD2 and the sequence of the chimeric gene (SEQ ID NO:25) was confirmed by DNA sequencing.

#### EXAMPLE 11

##### Transformation of Soybean with a Phaseolin-HSZ Chimeric Gene

To induce somatic embryos, cotyledons, 4-5 mm in length dissected from surface sterilized, immature seeds of the soybean cultivar XP3015, were cultured in the dark at 25°C on an agar medium (SB1 or SB2) for 8-10 weeks. Somatic embryos, which produced secondary embryos were excised and placed into a liquid medium (SB55). After repeated selection for clusters of somatic embryos which multiplied as early, globular staged embryos, the suspensions were maintained as described below.

Soybean embryogenic suspension cultures were maintained in 35 mL liquid media (SB55) on a rotary

shaker, 150 rpm, at 28°C with mixed florescent and incandescent lights on a 16:8 hour day/night schedule. Cultures were subcultured every four weeks by inoculating approximately 35 mg of tissue into 35 mL of liquid medium.

Soybean embryogenic suspension cultures were transformed by the method of particle gun bombardment (Kline et al. (1987) Nature (London) 327:70, U.S. Patent No. 4,945,050). A Du Pont Biolistic® PDS1000/HE instrument (helium retrofit) was used for these transformations.

The plasmid vector used for transformation was a derivative of pGEM9Z (Promega Biological Research Products). As a selectable marker a chimeric gene composed of the 35S promoter from Cauliflower Mosaic Virus [Odell et al. (1985) Nature 313:810-812], the hygromycin phosphotransferase gene from plasmid pJR225 (from *E. coli*) [Gritz et al. (1983) Gene 25:179-188] and the 3' region of the nopaline synthase gene from the T-DNA of the Ti plasmid of Agrobacterium tumefaciens (SEQ ID NO:26) was at the Sal I site of the vector. The phaseolin-HSZ chimeric gene cassette, phaseolin 5' region/phaseolin signal sequence/mature HSZ/phaseolin 3' region, (Example 6) was isolated as an approximately 2.3 kb Hind III fragment. This fragment was inserted into the unique Hind III site of the vector.

To 50 µL of a 60 mg/mL 1 µm gold particle suspension was added (in order); 5 µL DNA (1 µg/µL), 20 µL spermidine (0.1 M), and 50 µL CaCl<sub>2</sub> (2.5 M). The particle preparation was agitated for three minutes, spun in a microfuge for 10 seconds and the supernatant removed. The DNA-coated particles were then washed once in 400 µL 70% ethanol and resuspended in 40 µL of anhydrous ethanol. The DNA/particle suspension was sonicated three times for one second each. Five µL of

the DNA-coated gold particles were then loaded on each macro carrier disk.

Approximately 300-400 mg of a four-week-old suspension culture was placed in an empty 60x15 mm petri dish and the residual liquid removed from the tissue with a pipette. For each transformation experiment, approximately 5-10 plates of tissue are normally bombarded. Membrane rupture pressure was set at 1000 psi and the chamber was evacuated to a vacuum of 28 inches mercury. The tissue was placed approximately 3.5 inches away from the retaining screen and bombarded three times. Following bombardment, the tissue was placed back into liquid and cultured as described above.

Seven days post bombardment, the liquid media was exchanged with fresh SB55 containing 50 mg/mL hygromycin. The selective media was refreshed weekly. Seven weeks post bombardment, green, transformed tissue was observed growing from untransformed, necrotic embryogenic clusters. Isolated green tissue was removed and inoculated into individual flasks to generate new, clonally propagated, transformed embryogenic suspension cultures. Thus each new line was treated as an independent transformation event. These suspensions could then be subcultured and maintained as clusters of immature embryos or regenerated into whole plants by maturation and germination of individual somatic embryos.

Transformed embryogenic clusters were removed from liquid culture and placed on a solid agar media (SB103) containing no hormones or antibiotics. Embryos were cultured for eight weeks at 26°C with mixed florescent and incandescent lights on a 16:8 hour day/night schedule. During this period, individual embryos were removed from the clusters and analyzed for production of

the HSZ protein as described below. After eight weeks, the embryos are suitable for germination.

Individual embryos were frozen in liquid nitrogen, and ground to a fine powder with a mortar and pestle  
5 prechilled in liquid nitrogen. The powder was scraped into an eppendorf centrifuge tube and extracted twice with hexane at room temperature. The residue was incubated at 60°C for 30 min to allow residual hexane to evaporate. Then 100 µL of 50 mM Tris-HCl pH6.7, 2mM  
10 EDTA, 1% SDS 1% β-mercaptoethanol (TESβ) was added to the pellet and it was ground at low speed for about 10 sec using a motorized grinder with disposable plastic shafts designed to fit into the microfuge tube. The resultant suspensions were centrifuged for 5 min at room  
15 temperature in a microfuge and the supernatant was removed and saved. The pellet was resuspended in 50 µL of 70% isopropanol, 10mM β-mercaptoethanol by grinding as above. The tube was incubated at 60°C for 5 min and centrifuged as above. The supernatant was saved and the  
20 pellet extracted again with 50 µL of 70% isopropanol, 10mM β-mercaptoethanol. The alcohol extracts were pooled and lyophilized; the residue was then resuspended in 50 µL of TESβ. This sample and the first TESβ extract were assayed for the presence of HSZ protein by  
25 Western blot as described in Example 9. Two of three transformed lines tested showed expression of HSZ protein.

EXAMPLE 12Transformation of Maize with a High-Sulfur  
Storage Protein Gene

Callus cultures were initiated from immature  
5 embryos (about 1.5 to 2.0 mm) dissected from kernels  
derived from crosses of the genotypes A188 and B73 10 to  
12 days after pollination. The embryos were placed with  
the axis-side facing down and in contact with agarose-  
solidified N6 medium. The embryos were kept in the dark  
10 at 27°C. Friable embryogenic callus consisting of  
undifferentiated masses of cells with somatic  
proembryoids and embryoids borne on suspensor structures  
proliferates from the scutellum of these immature  
embryos. The embryogenic callus isolated from the  
15 primary explant was cultured on N6 medium and sub-  
cultured on this medium every 2 to 3 weeks.

The particle bombardment method was used to  
transfer genes to the callus culture cells. A  
Biolistic® PDS-1000/He (BioRAD Laboratories, Hercules,  
20 CA) was used for these experiments.

A plasmid vector containing a selectable marker  
gene was used in the transformations. The plasmid,  
pALSLUC [Fromm et al. (1990) Biotechnology 8:833-839],  
contains a cDNA of the maize acetolactate synthase (ALS)  
25 gene. The ALS cDNA had been mutated in vitro so that  
the enzyme coded by the gene would be resistant to  
chlorsulfuron. The change consisted of mutating a  
tryptophan codon at position 1626 of the cDNA to a  
leucine codon. The ALS gene is under the control of the  
30 35S promoter from Cauliflower Mosaic Virus [Odell et  
al., (1985) Nature 313:810-812] and the 3U region of the  
nopaline synthase gene from the T-DNA of the Ti plasmid  
of Agrobacterium tumefaciens. This plasmid also  
contains a gene that uses the 35S promoter from  
35 Cauliflower Mosaic Virus and the 3U region of the

nopaline synthase gene to express a firefly luciferase coding region [de Wet et al. (1987) Molec. Cell Biol. 7:725-737]. The chimeric HSZ gene was delivered on a second plasmid. This plasmid (pCC21, see EXAMPLE 6) contains the HSZ coding region under the control of the promoter region and the 3U end from the gene that codes for the 10 kd storage protein gene from maize [Kirihara et al. (1988) Gene 71:359-370].

These plasmids (pALSLUC and pCC21) were co-precipitated onto the surface of gold particles. To accomplish this 5  $\mu$ g of pALSLUC and 2  $\mu$ g of pCC21 (each in Tris-EDTA buffer at a concentration of about 1  $\mu$ g/ $\mu$ L) were added to 50  $\mu$ L of gold particles (average diameter of 1.5  $\mu$ m) suspended in water (60 mg of gold per mL). Calcium chloride (50  $\mu$ L of a 2.5 M solution) and spermidine (20  $\mu$ L of a 1.0 M solution) were then added to the gold-DNA suspension as the tube was vortexing. The particles were then centrifuged in a microfuge for 10 seconds and the supernatant removed. The particles were then resuspended in 200  $\mu$ L of absolute ethanol. The particles were centrifuged again and the supernatant removed. The particles were then resuspended in 30  $\mu$ L of ethanol. Five  $\mu$ L of the DNA-coated gold particles were then loaded on each macro carrier disk.

Small clusters (2 to 3 mm in diameter) of embryogenic callus was arranged on the surface of agarose-solidified N6 medium contained in a petri dish 12 cm in diameter. The tissue covered a circular area of about 6 cm in diameter. The petri dish containing the tissue was placed in the chamber of the PDS-1000/He. The air in the chamber was then evacuated to a vacuum of 28 inch of Hg. The macrocarrier was accelerated with a helium shock wave using a rupture membrane that bursts when the He pressure in the shock tube reaches 1000 psi. The tissue was placed approximately 8 cm from the

stopping screen. Ten plates of tissue were bombarded with the DNA-coated gold particles.

Seven days after bombardment the tissue was transferred to N6 medium that contained chlorsulfuron (50 nM) and lacked casein or proline. The tissue continued to grow slowly on this medium. After an additional 2 weeks the tissue was transferred to fresh N6 medium containing chlorsulfuron. After 8 weeks an area of about 1 cm in diameter of actively growing callus was identified on one of the plates containing chlorsulfuron-supplemented medium. This callus continued to grow when sub-cultured on the selective medium. Some of this callus has been transferred to medium that allows plant regeneration.

Luciferase activity was measured in this callus. Untransformed callus tissue has luciferase activity of about 500 light units per mg of fresh tissue. The callus that grew on chlorsulfuron had luciferase activity of about 20,000 light units per mg of fresh tissue. This result indicates that genes from pALSLUC are expressed in this callus line. Southern analysis was performed for the presence of both the introduced ALS gene and the introduced chimeric storage protein gene. Both introduced genes were observed by Southern analysis.

For analysis of the HSZ gene, genomic DNA from the transformed callus line (Tx-X8A) or callus derived from the same genotype but that was not transformed (AB91) was digested with either Xba I or EcoR I. The digested DNA was fractionated by gel electrophoresis through agarose and transferred to a nylon membrane using standard techniques. The nylon blot was hybridized to a probe prepared from a part of the HSZ coding region. AB91 callus exhibited one dominant band that corresponds to the native HSZ gene. An additional band of higher

molecular weight was found in the Tx-X8A callus. This band corresponds to the introduced chimeric HSZ gene.

SEQUENCE LISTING

- (1) GENERAL INFORMATION:
- (i) APPLICANT: SAVERIO C. FALCO  
CHOK-FUN CHUI  
JANET A. RICE
  - (ii) TITLE OF INVENTION: A HIGH SULFUR SEED  
PROTEIN GENE AND  
METHOD FOR INCREASING  
THE SULFUR AMINO ACID  
CONTENT OF PLANTS
  - (iii) NUMBER OF SEQUENCES: 28
  - (iv) CORRESPONDENCE ADDRESS:
    - (A) ADDRESSEE: E. I. DU PONT DE NEMOURS  
AND COMPANY
    - (B) STREET: 1007 MARKET STREET
    - (C) CITY: WILMINGTON
    - (D) STATE: DELAWARE
    - (E) COUNTRY: U.S.A.
    - (F) ZIP: 19898
  - (v) COMPUTER READABLE FORM:
    - (A) MEDIUM TYPE: DISKETTE, 3.50 INCH, 1.0MB
    - (B) COMPUTER: MACINTOSH
    - (C) OPERATING SYSTEM: MACINTOSH SYSTEM, 6.0
    - (D) SOFTWARE: MICROSOFT WORD, 4.0
  - (vi) CURRENT APPLICATION DATA:
    - (A) APPLICATION NUMBER:
    - (B) FILING DATE:
    - (C) CLASSIFICATION:
  - (vii) PRIOR APPLICATION DATA:
    - (A) PRIORITY DATE: 14 FEBRUARY 1991
    - (B) USSN: 07/656,687
  - (viii) ATTORNEY/AGENT INFORMATION:
    - (A) NAME: Linda Axxamethy Floyd
    - (B) REGISTRATION NUMBER: 33,692
    - (C) REFERENCE/DOCKET NUMBER: BB-1027-A

## (ix) TELECOMMUNICATION INFORMATION:

(A) TELEPHONE: (302) 992-4929  
(B) TELEFAX: (302) 892-7949  
(C) TELEX: 835420

## (2) INFORMATION FOR SEQ ID NO:1:

## (i) SEQUENCE CHARACTERISTICS:

(A) LENGTH: 2123 nucleotides  
(B) TYPE: DNA  
(C) STRANDEDNESS: single  
(D) TOPOLOGY: linear

(ii) MOLECULE TYPE: genomic DNA

(iii) HYPOTHETICAL: NO

(iv) ANTI-SENSE: NO

(v) FRAGMENT TYPE:

## (vi) ORIGINAL SOURCE:

(A) ORGANISM: Zea mays L  
(B) STRAIN: unknown  
(C) CELL TYPE: unknown

## (vii) IMMEDIATE SOURCE:

(A) LIBRARY: maize genomic library  
obtained from Clontech  
(B) CLONE: X8

(viii) POSITION IN GENOME: unknown

(x) PUBLICATION INFORMATION: unpublished sequence

<b>MICROORGANISMS</b>	
Optional Sheet in connection with the microorganism referred to on page <u>18</u> , line <u>10</u> of the description.	
<b>A. IDENTIFICATION OF DEPOSIT</b> Further deposits are identified on an additional sheet <input type="checkbox"/>	
Name of depository institution:  American Type Culture Collection	
Address of depository institution (including postal code and country): 12301 Parklawn Drive Rockville, Maryland 20852 US	
Date of deposit: 7 December 1990	Accession Number: 68490
<b>B. ADDITIONAL INDICATIONS</b> (none more if not applicable). This information is continued on a separate attached sheet <input type="checkbox"/>	
<p>"In respect of those designations in which a European patent is sought, a sample of the deposited microorganism will be made available until the publication of the mention of the grant of the European patent or until the date on which the application has been refused or withdrawn or is deemed to be withdrawn, only by the issue of such a sample to an expert nominated by the person requesting the sample. (Rule 28(4) EPC)"</p>	
<b>C. DESIGNATED STATES FOR WHICH INDICATIONS ARE MADE</b> (If the indications are not for all designated States)	
<b>D. SEPARATE FURNISHING OF INDICATIONS</b> (none more if not applicable)	
The indications noted below will be submitted to the International Bureau later (Specify the general nature of the indications e.g., "Accession Number of Deposit")	
<b>E.</b> <input type="checkbox"/> This sheet was received with the international application when filed (to be checked by the receiving Office)	
<b>FRANCE L. BONNET</b> <b>INTERNATIONAL DIVISION</b> (Authorized Officer)	
<input type="checkbox"/> The date of receipt (from the applicant) by the International Bureau is:	
(Authorized Officer)	

CLAIMS

What is claimed is:

5

1. An isolated and purified nucleic acid fragment comprising at least one nucleotide sequence corresponding to or substantially homologous to the sequence shown in SEQ ID NO:2 encoding "HSZ corn seed storage protein".

10

2. An isolated and purified nucleic acid fragment comprising at least one nucleotide sequence corresponding to or substantially homologous to the sequence shown in SEQ ID NO:3 encoding "mature HSZ corn seed storage protein".

15

3. An isolated and purified nucleic acid fragment comprising at least one nucleotide sequence corresponding to or substantially homologous to the sequence shown in SEQ ID NO:4 encoding "HMD corn seed storage protein".

20

4. The nucleic acid fragment of Claim 2 operably linked to a signal sequence from a dicotyledonous plant.

25

5. The nucleic acid fragment of Claim 3 operably linked to a plant signal sequence.

6. A chimeric gene capable of causing altered levels of sulfur amino acid in transformed plants, the chimeric gene comprising the nucleic acid fragment of any of Claims 1-5 operably linked to an intracellular localization sequence and a suitable regulatory sequence.

30

35

7. The chimeric gene of Claim 6 wherein the regulatory sequence is selected from the group consisting of seed-specific regulatory sequences.

5

8. A plant transformed with the chimeric gene of Claim 6.

9. A plant according to Claim 8 wherein the plant is selected from the group consisting of corn, soybean, canola, tobacco, and rice.

10. Seeds obtained from the plants of Claim 8.

11. A chimeric gene capable of causing altered levels of sulfur amino acids in transformed microorganisms, the chimeric gene comprising the nucleic acid fragment of Claims 2 or 3 operably linked to a suitable regulatory sequence.

20

12. A microorganism transformed with the chimeric gene of Claim 11.

13. A polypeptide product of the expression in a procaryotic or eucaryotic host cell of a nucleic acid fragment according to Claims 1, 2 or 3.

25

14. A plant containing the polypeptide product of Claim 13.

30

15. A seed containing the polypeptide product of Claim 13.

16. A method for increasing the sulfur amino acid content of plants comprising:

35

(a) transforming a plant cell with the chimeric gene of Claim 6;

(b) growing fertile, sexually mature plants from said transformed plant cell; and

5 (c) selecting progeny seed from said fertile plants for increased levels of sulfur amino acids relative to untransformed plant cells.

17. A method for producing protein rich in sulfur-  
10 containing amino acids in a microorganism comprising:

(a) transforming a microorganism with the chimeric gene of Claim 11;

(b) growing said microorganism under conditions for expression of protein rich in sulfur-  
15 containing amino acids; and

(c) isolating the protein of step (b).

18. Essentially pure plasmid pCC10, said plasmid comprising the nucleic acid fragment of Claim 1, and  
20 identified by the deposit accession number ATCC 68490.

## INTERNATIONAL SEARCH REPORT

International Application No

PCT/US 92/00958

<b>I. CLASSIFICATION OF SUBJECT MATTER</b> (If several classification symbols apply, indicate all) <sup>6</sup>		
According to International Patent Classification (IPC) or to both National Classification and IPC		
Int.Cl. 5	C12N15/29; C12P21/02	C12N15/82; A01H5/00; C07K13/00
<b>II. FIELDS SEARCHED</b>		
Minimum Documentation Searched <sup>7</sup>		
Classification System	Classification Symbols	
Int.Cl. 5	C07K ; C12N ; C12P ; A01H	
Documentation Searched other than Minimum Documentation to the Extent that such Documents are Included in the Fields Searched <sup>8</sup>		
<b>III. DOCUMENTS CONSIDERED TO BE RELEVANT<sup>9</sup></b>		
Category <sup>10</sup>	Citation of Document, 11 with indication, where appropriate, of the relevant passages <sup>12</sup>	Relevant to Claim No. <sup>13</sup>
A	GENE. vol. 71, 1988, AMSTERDAM NL pages 359 - 370; KIRIHARA, J. A., ET AL.,: 'Isolation and sequence of a gene encoding a methionine-rich 10-kDa zein protein from maize' cited in the application see the whole document ---	1-4
A	TRENDS IN BIOTECHNOLOGY vol. 8, no. 6, June 1990, pages 156 - 160; ALTENBACH, S. B., ET AL.,: 'Manipulation of methionine-rich protein genes in plant seeds' see the whole document --- -/-	1-16
<p>* Special categories of cited documents :<sup>10</sup></p> <p>"A" document defining the general state of the art which is not considered to be of particular relevance</p> <p>"E" earlier document but published on or after the international filing date</p> <p>"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)</p> <p>"O" document referring to an oral disclosure, use, exhibition or other means</p> <p>"P" document published prior to the international filing date but later than the priority date claimed</p> <p>"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention</p> <p>"X" document of particular relevance; the claimed invention<sup>14</sup> cannot be considered novel or cannot be considered to involve an inventive step</p> <p>"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.</p> <p>"A" document member of the same patent family</p>		
<b>IV. CERTIFICATION</b>		
Date of the Actual Completion of the International Search	Date of Mailing of this International Search Report	
27 MAY 1992	05. 06. 92	
International Searching Authority	Signature of Authorized Officer	
EUROPEAN PATENT OFFICE	MADDOX A.D.	

III. DOCUMENTS CONSIDERED TO BE RELEVANT (CONTINUED FROM THE SECOND SHEET)		
Category *	Citation of Document, with indication, where appropriate, of the relevant passages	Relevant to Claim No.
A	JOURNAL OF BIOTECHNOLOGY. vol. 2, 1985, AMSTERDAM NL pages 157 - 175; NORRANDER, J. M., ET AL.: 'Manipulation and expression of the maize storage proteins in Escherichia coli' see the whole document ---	11,12,17
A	PLANT MOLECULAR BIOLOGY. vol. 12, 1989, DORDRECHT, THE NETHERLANDS. pages 123 - 130; MASUMURA, T., ET AL.: 'cDNA cloning of an mRNA encoding a sulfur-rich 10kDa prolamin polypeptide in rice seeds' cited in the application see page 125, left column, paragraph 1 ---	11,12,17
